# $\pi_{1}$ of smooth points of a log del Pezzo surface is finite : I 

By R. V. Gurjar and D.-Q. Zhang

#### Abstract

A log del Pezzo surface is a normal projective surface $S$ defined over the field of complex numbers, such that $S$ has at most quotient singularities and $-K_{S}$ is ample, where $K_{S}$ denotes the canonical divisor. The main result of this work is the following theorem:

Theorem. Let $S$ be a log del Pezzo surface. Then the fundamental group of the space of smooth points of $S$ is finite.

We also give a quite precise description of the singularities of $S$ when $S$ has Picard group of rank 1.

## Introduction

A normal projective surface $S$ over $\mathbf{C}$ is called a log del Pezzo surface if $S$ has at worst quotient singularities and $-K_{S}$ is ample, where $K_{S}$ denotes the canonical divisor of $S$.

Recall that the divisor class group of a quotient singularity is always finite. Hence for any Weil divisor $D$ on a $\log$ del Pezzo surface $S, n D$ is a Cartier divisor for some integer $n \geq 1$.

The principal result of this paper is the following:
Main Theorem. The fundamental group of the space of smooth points of a log del Pezzo surface is finite.

In the case of a Gorenstein log del Pezzo surface, this result was proved in [13] by first classifying such surfaces.In this paper, we also give a very easy proof of the result in the case of Gorenstein log del Pezzo surfaces. So far, there are not many results about general log del Pezzo surfaces. Recently,

[^0]V.A. Alekseev and V.V. Nikulin have classified all log del Pezzo surfaces of index $\leq 2$ (i.e., where $2 K_{S}$ is Cartier)(cf. [1]).

The index of a $\log$ del Pezzo surface $S$ is defined to be the smallest positive integer $n$ such that $n K_{S}$ is a Cartier divisor. In [15], Nikulin has proved that the rank of the Picard group of a minimal resolution of $S$ is bounded by a universal function of the index of $S$. From this also one can deduce Proposition 1.7 below.
M. Miyanishi has made the following:

Conjecture Let $S$ be a log del Pezzo surface of rank 1. Then there is a finite unramified covering of $S-S i n g S$ which contains a Zariski-open subset isomorphic to $C \times \mathbf{A}^{1}$, where $C$ is a smooth curve.

It follows easily from the Lemmas 1.2 and 2.2 of this paper that if Miyanishi's conjecture is true then the Main Theorem of this paper is true. The Main Theorem thus lends a partial support to Miyanishi's conjecture.

Due to the length of the proof of the Main Theorem, this paper is being written in two parts. We will now give some indication of key ideas used in the proof.

Following an important idea of Miyanishi and Tsunoda, in $\S 3$ we use a "minimal" $(-1)$ curve $C$ on the minimal resolution of singularities, $\widetilde{S}$, of $S$. Using the assumption that $-K_{S}$ is ample we analyse the intersection behavior of the exceptional divisor $D$ with $C$. The proof splits into two main cases according as the linear system $\left|K_{\widetilde{S}}+C+D\right|$ is empty or nonempty. The bulk of the paper goes into handling the first case. The first case itself splits into the " 2 -component" case and the " 3 -component" case. The part II of this paper deals exclusively with the " 2 "-component" case. It should be remarked that we can prove much more precise results about the intersection behavior of $C$ and $D$ than given in $\S 6$, but the Main Theorem stated above has been our main goal in this paper and so we have given only those details which are crucial for the proof (cf. the remark after the proof of Theorem 6.14). Several sub- cases from the "3-component" case are reduced to the "2- component" case. We could have given a self-contained proof for the "3-component" case, but this would have made the proof even more technical. As a consequence, the proof of the Main Theorem (even in the "3-component" case) is completed only in the part II of this paper.

The main ingredients in the proof of the Main Theorem are the following :

1) Several results of the paper [18]. The lemmas 1.5, 1.6 from [18]are frequently used.
2) A reduction to the case when the Picard group of $S$ is infinite cyclic.
3) A somewhat precise information about the configuration of singular points when Pic $S \simeq \mathbf{Z}$.
4) A version of the Lefschetz hyperplance section theorem for fundamental groups given in [16].
5) A version of Van- Kampen's theorem for non-connected intersections due to P. Wagreich.

There are easy examples of normal projective rational surfaces over $\mathbf{C}$ with quotient singularities (even double points) and with numerically effective anti-canonical divisor,such that the fundamental group of the space of smooth points is infinite. See $\S 1.15$. This shows that the condition about the ampleness of $-K_{S}$ in the Main Theorem cannot be dropped.

From the Main theorem, we see easily that any log del Pezzo surface $S$ is a quotient of a log del Pezzo surface $T$ modulo a finite group such that the space of smooth points of $T$ is simply-connected (the group acting freely outside a finite set of points of $T$ ).

Acknowledgements. This work was started when both the authors were visiting the Max Planck Institut für Mathematik in Bonn. We are very much thankful to the Max Planck Institut and to Prof.F. Hirzebruch for the financial support and hospitality.

## §1. Some easy results

In this section we fix the following notations and terminology which will be used throughout the paper.

Let $S$ be a log del Pezzo surface as defined in the introduction. Denote by $S^{o}:=S-(\operatorname{Sing} S)$ the smooth part of $S$. Let $f: \widetilde{S} \rightarrow S$ be a minimal resolution of singularities and denote by $D:=f^{-1}(\operatorname{Sing} S)$ the exceptional divisor. A divisor $H$ on $\widetilde{S}$ is numerically effective (nef, for short) if and only if $H \cdot \Delta \geq 0$ for any curve $\Delta$ on $\widetilde{S}$. A nef divisor $H$ is $\operatorname{big}$ if $\left(H^{2}\right)>0$. By a $(-n)$ - curve on $\widetilde{S}$ we mean a nonsingular rational curve of self intersection $-n$.
$K_{S}$ : canonical divisor of $S$.
$f^{*}(H)$ : total transform of $H$ by $f$.
$f^{\prime}(H)$ : proper transform of $H$ by a birational morphism $f$.
$H_{1} \sim H_{2}$ : linear equivalence.
$H_{1} \equiv H_{2}$ : numerical equivalence.
$\# H$ : the number of irreducible components of Supp $H$.
The dual graphs of minimal resolutions of quotient singularities are classified in [2].

Write $D=\sum_{i=1}^{n} D_{i}$ where $D_{i}$ is irreducible.The first part of Lemma 1.1 below follows from the definition of a quotient singularity. The second part is trivial and the third part follows from the ampleness of $-K_{S}$ (cf. [9]).

Lemma 1.1. (1) There exists a $\mathbf{Q}$-coefficient divisor $D^{*}=\sum_{i=1}^{n} \alpha_{i} D_{i}$ such that $0 \leq \alpha_{i}<1$ and

$$
f^{*}\left(K_{S}\right) \equiv K_{\widetilde{S}}+D^{*}
$$

Moreover, $\alpha_{j}=0$ if and only if the connected component of $D$ containing $D_{j}$ is contracted to a rational double point on $S$.
(2) Let $p$ be the smallest positive integer such that $p D^{*}$ is an integral divisor. Then $p K_{S}$ is a Cartier divisor and

$$
f^{*}\left(p K_{S}\right) \sim p\left(K_{\widetilde{S}}+D^{*}\right)
$$

(3) $-\left(K_{\widetilde{S}}+D^{*}\right)$ is a nef and big divisor.Moreover, $-\left(K_{\widetilde{S}}+D^{*}\right) \cdot B=0$ if and only if the support of $B$ is contained in $D$.
(4) Suppose that $B$ is an irreducible curve on $\widetilde{S}$ with negative self intersection. Then either $B$ is a (-1)-curve or $B \leq D$.

Proof. (1), (2), (3) are well-known results for quotient singularities.(See [9]).
(4) Suppose that $B$ is not contained in $D$. Then $B . K_{\widetilde{S}}<0$ by (3). Now it follows from the genus formula that $B$ is a $(-1)$-curve.

Lemma 1.2. Let $T$ be a normal projective surface with a finite morphism $\varphi: T \rightarrow S$ which is unramified over $S^{\circ}$. Then $T$ is a log del Pezzo surface.

Proof. If $T^{o}=T-(\operatorname{Sing} T)$, then clearly $K_{T^{o}} \sim \varphi^{*}\left(K_{S^{o}}\right)$. This implies that $K_{T} \sim \varphi^{*}\left(K_{S}\right)$. Since $-K_{S}$ is ample, $-K_{T}$ is also ample. Since
$\varphi$ is unramified over $S^{o}$, the local fundamental group of $T$ at any point is finite. Hence $T$ is a $\log$ del Pezzo surface.

Lemma 1.3. A log del Pezzo surface is rational.
Proof. Let $f: \widetilde{S} \rightarrow S$ be as in the beginning of this section. Then for a suitable large integer $p,-p\left(K_{\widetilde{S}}+D^{*}\right)$ is a Cartier divisor linearly equivalent to a nonzero effective divisor $\Delta$. Hence $\left|p K_{\widetilde{S}}\right|=\phi$. Now $\widetilde{S}$ is a ruled surface or $\mathbf{P}^{2}$.

Suppose $\widetilde{S}$ is a ruled surface with a morphism $\varphi: \widetilde{S} \rightarrow B$ onto a smooth projective curve $B$ such that a general fiber of $\varphi$ is $\mathbf{P}^{1}$.

First we consider the case where one of the irreducible components of $D$ maps surjectively onto $B$ under $\varphi$. In this case $B \approx \mathbf{P}^{1}$ and $\widetilde{S}$ is rational.

Now we assume that $D$ is contained in a union of fibers of $\varphi$. We have an induced $\mathbf{P}^{1}$-fibration $\varphi^{\prime}: S \rightarrow B$. Clearly, rank $S \geq 2$. We borrow part of the argument from the proof of Lemma 2.1. We argue by induction on rank $S$.

By Kawamata's contraction theorem [cf. 10,§ 3-2] , there is a contraction $\sigma: S \rightarrow Y$, where $Y$ is a normal projective variety obtained by contraction of an extremal face. If $Y$ is a surface then rank $Y<\operatorname{rank} S$ and $Y$ is a log del Pezzo surface. By induction, $Y$ and hence $S$ is rational.

Suppose $Y$ is a non-singular curve. If an irreducible curve which is a multisection for $\varphi^{\prime}$ is mapped to a point by $\sigma$, then that "horizontal" curve is a rational curve and hence $B$ is rational. Assume now that an irreducible curve $C$ contained in a fiber of $\varphi^{\prime}$ is mapped to a point by $\sigma$. As $C$ generates an extremal ray, we see that every fiber of $\varphi^{\prime}$ is irreducible and $\varphi^{\prime}$ is the contraction map. Thus $Y=B$.

Suppose $Y$ is not a rational curve. Using a branched covering $Z \rightarrow Y$ as in the proof of Case 2 in Lemma 2.1 ( using Fox's result) with suitable ramification divisor on $Y$ and Lemma 1.2, we see that $S_{1}=\overline{S \times_{Y} Z}$ is a $\log$ del Pezzo surface with a $\mathbf{P}^{1}$-fibration $\varphi^{\prime \prime}: S_{1} \rightarrow Z$. All the fibers of $\varphi^{\prime \prime}$ are reduced. Hence we can now assume that $\varphi^{\prime}$ itself has all the fibers reduced. Now $\widetilde{S}$ is obtained from a minimal ruled fibration $\psi: X \rightarrow B$ by a composition of blowing ups. Using the fact that all the fibers of $\varphi^{\prime}$ are reduced, we see that the contraction $\widetilde{S} \rightarrow X$ can be so chosen that we have an induced morphism $S \rightarrow X$. But then $S=X$. We have $K_{S}^{2}=8(1-g)$,
where $g$ is the genus of $B$. From the ampleness of $K_{S}$ we know that $K_{S}^{2}>0$. Hence $g=0$ and $B$ is rational.

This completes the proof of Lemma 1.3.
Lemma 1.4. $H_{1}\left(S^{o}, \mathbf{Z}\right)$ is finite.
Proof. By Lemma $1.3, \widetilde{S}$ is rational and hence $H_{1}(\widetilde{S}, \mathbf{Z})=0$. We consider the long exact cohomology sequence of the pair $(\widetilde{S}, D)$ with integral coefficients:

$$
H^{2}(\widetilde{S}) \rightarrow H^{2}(D) \rightarrow H^{3}(\widetilde{S}, D) \rightarrow H^{3}(\widetilde{S}) \rightarrow(0)
$$

By Poincaré duality, $H^{3}(\widetilde{S}, D)$ is isomorphic to $H_{1}\left(S^{0}\right)$.
The irreducible components of $D$ give linearly independent homology classes in $\mathrm{H}_{2}(\widetilde{S})$ as the intersection matrix of $D$ is negative definite. From this we see that the cokernel of the map $H^{2}(\widetilde{S}) \rightarrow H^{2}(D)$ is finite. By Poincaré duality, $H^{3}(\widetilde{S}) \cong H_{1}(\widetilde{S})=(0)$. Now the result follows.

Lemma 1.5. $\bar{\kappa}\left(S^{o}\right)=-\infty$, where $\bar{\kappa}$ is the logarithmic Kodaira dimension as defined by S. Iitaka (cf. [8]).

Proof. Suppose $\left|n\left(K_{\widetilde{S}}+D\right)\right| \neq \phi$ for some $n \geq 1$. Since $-n\left(K_{\widetilde{S}}+D^{*}\right)$ is a nef and big Cartier divisor for some integer $n \gg 0$, the complete linear system $\left|n\left(K_{\widetilde{S}}+D\right)-n\left(K_{\widetilde{S}}+D^{*}\right)\right|$ has dimension $\geq 1$. This contradicts the negative definiteness of the intersection matrix of $D$.

Remark 1.6. If the Picard group of $S$ has rank one, then M. Miyanishi has proved the converse of Lemma 1.5 viz. in this case, if $\bar{\kappa}\left(S^{o}\right)=-\infty$, then $S$ is a $\log$ del Pezzo surface (cf. [18, Remark 1.2]). This result is false if the rank of Pic $S$ is bigger than one (cf. Example in $\S 1.15$ ).

The next result is a very useful step in the proof of the Main Theorem of this paper.

Proposition 1.7. The algebraic fundamental group of $S^{\circ}$ is finite.
Proof. We have to show that $S^{o}$ does not have finite unramified covers of arbitrarily large degrees.

So, suppose that $\cdots \rightarrow S_{n} \rightarrow S_{n-1} \rightarrow \cdots \rightarrow S_{0}:=S$ is a sequence of finite Galois covers of $S$ unramified over $S^{o}$. Let $q$ be any singular point of $S$. Then all the points in $S_{n}$ lying over $q$ are conjugate to each other under the Galois group of $S_{n}$ over $S$. The local fundamental groups of $S_{n}$ at these points are then mutually isomorphic and isomorphic to a subgroup of the local fundamental group of $S$ at $q$.

From this observation we see easily that the local fundamental groups of $S_{n}$ get stabilized if $n \gg 0$ at every point of $S_{n}$ over $S-S^{0}$. Hence the maps $S_{n} \rightarrow S_{n-1}$ are unramified for large $n$. By Lemma 1.2 each $S_{n}$ is a log del Pezzo surface and hence rational by Lemma 1.3. But any normal projective rational surface is simply-connected. Thus $S_{n} \rightarrow S_{n-1}$ is an isomorphism for large $n$. This proves the result.

In the remaining part of this section we collect together some known results which will be used crucially in the proof of the theorem.

The following result is proved in [11, Chapter 1, §2.1.2].
Let $X$ be a smooth projective rational surface and $\Delta=\Delta_{1}+\cdots \Delta_{r}$ be a reduced divisor with irreducible components $\Delta_{i}$.

Let $m$ be the number of connected components of $\operatorname{Supp}(\Delta)$.
Let $e(\Delta)=m-r+\Sigma_{i<j} \Delta_{i} \cdot \Delta_{j}$, which is clearly a nonnegative integer.
Lemma 1.8. $\operatorname{dim} H^{0}\left(X, O\left(K_{X}+\Delta\right)\right)=\sum_{i=1}^{r} p_{a}\left(\Delta_{i}\right)+e(\Delta)$. Further, $H^{0}\left(X, O\left(K_{X}+\Delta\right)\right)=0$ if and only if Supp $\Delta$ is a normal crossing divisor of nonsingular rational curves such that each connected component of Supp $\Delta$ is a tree.

The following two results are proved by Madhav Nori in [16].
Lemma 1.9. Let $X$ be a nonsingular quasi-projective surface with a surjective morphism $\varphi: X \rightarrow B$, where $B$ is a nonsingular curve. Assume that the general fiber $F$ of $\varphi$ is connected and each scheme-theoretic fiber of $\varphi$ contains a reduced irreducible component. Then the following sequence is exact:

$$
\pi_{1}(F) \rightarrow \pi_{1}(X) \rightarrow \pi_{1}(B) \rightarrow(1)
$$

The next result is a very useful version of Lefschetz hyperplane section theorem.

Lemma 1.10. Let $X$ be a nonsingular projective surface and $\Delta$ any effective divisor on $X$ such that the Iitaka $D$-dimension $\kappa(X, \Delta) \geq 2$. Let
$R \subset X$ be any proper Zariski closed subset. Then for any open neighbourhood $U$ of $\Delta$, the homomorphism $\pi_{1}(U-R) \rightarrow \pi_{1}(X-R)$ is surjective.

Using Lemma 1.10, we will now give an easy proof of the special case of the Main Theorem when $S$ is Gorenstein. This was proved earlier in [12, 13] by first classifying such surfaces.

Proposition 1.11. Let $S$ be a Gorenstein log del Pezzo surface. Then $\pi_{1}\left(S^{o}\right)$ is abelian and finite.

Proof. By Lemma 1.4, it is enough to prove that $\pi_{1}\left(S^{o}\right)$ is abelian. By [4, Theorem 1, p.39],there is a non-singular elliptic curve $A \in\left|-K_{S}\right|$. Since $-K_{S}$ is ample and $K_{\widetilde{S}}=f^{*}\left(K_{S}\right)$, the Iitaka $D$-dimension $\kappa\left(\widetilde{S},-K_{\widetilde{S}}\right)=2$. Also $A$ is disjoint from $\operatorname{Sing} S$ as $S$ has only rational double points. Now by Lemma 1.10, we have a surjective map $\mathbf{Z} \times \mathbf{Z}=\pi_{1}(A) \rightarrow \pi_{1}(\widetilde{S}-D)$. Thus $\pi_{1}\left(S^{o}\right)$ is abelian.

Remark 1.12. The proof shows that if $\left|-K_{S}\right|$ contains a member $A$ which is a rational cuspidal curve disjoint from $\operatorname{Sing} S$ then $\pi_{1}\left(S^{o}\right)=(1)$ because $\pi_{1}(A)=(1)$.

The next result follows from the well-known result of Mumford giving the presentation of the fundamental group of the boundary of a nice tubular neighborhood of a tree of non-singular rational curves on a smooth complex surface. (cf. [14]).

Lemma 1.13 Let $X$ be a non-singular projective surface and $\Delta$ a connected normal crossing divisor on $X$ with all the irreducible components non-singular rational curves. Assume one of the following two conditions:
(1) The dual graph of $\Delta$ is linear and $\Delta$ supports a divisor with positive self-intersection.
(2) The dual graph of $\Delta$ has exactly one branch point and the three linear branches $T_{1}, T_{2}, T_{3}$ such that:
(i) $\Delta$ supports a divisor with positive self-intersection, and
(ii) the intersection form on $T_{1}+T_{2}+T_{3}$ is negative definite and $1 / d_{1}+$ $1 / d_{2}+1 / d_{3}>1$, where $d_{i}$ is the absolute value of the determinant of the intersection matrix of $T_{i}$.

If $U$ is a "nice" tubular neighborhood of $\Delta$ in $X$, then $\pi_{1}(U-\Delta)$ is finite.

We will need the following generalization of the Van-Kampen theorem proved by P. Wagreich (cf. [17,Prop. 2.1]).

Lemma 1.14 Suppose $A$ is a connected simplicial complex with connected subcomplexes $A_{0}, A_{1}$ such that $A=A_{0} \cup A_{1}, A_{0} \cap A_{1}=B_{0} \cup B_{1}$ where, $B_{i}$ is a connected subcomplex of $A_{j}$ for all $i, j$ and $B_{0} \cap B_{1}=\phi$. Let $\varphi_{i j}: \pi_{1}\left(B_{i}\right) \rightarrow \pi_{1}\left(A_{j}\right)$ be the map induced by the inclusion. Then $\pi_{1}(A)$ is isomorphic to $\pi_{1}\left(A_{0}\right) * \pi_{1}\left(A_{1}\right) * \mathbf{Z}(u) / G$ where, * denotes free product and $\mathbf{Z}(u)$ denotes the free group with one generator $u$ and $G$ is the normal subgroup generated by the relations:

$$
\varphi_{0,0}(b)=\varphi_{0,1}(b)
$$

for all $b \in \pi_{1}\left(B_{0}\right)$ and

$$
\varphi_{1,0}(b)=u^{-1} \varphi_{1,1}(b) u
$$

for all $b \in \pi_{1}\left(B_{1}\right)$.

### 1.15. An example

Let $\sigma$ be an involution which acts diagonally and non-trivially on each factor of the product $\mathbf{P}^{1} \times E$, where $E$ is an elliptic curve and let $T$ be the quotient of this product modulo $\sigma$. Then $T$ has only singularities of type $A_{1}$. The quotient morphism $g$ is unramified over the smooth part of $T$. It follows that the fundamental group of $T-\operatorname{Sing} T$ is infinite. Clearly, $g^{*}\left(K_{T}\right) \simeq K_{\mathbf{P}^{1} \times E}$. Hence we see by projection formula that $-K_{T}$ is numerically effective but not big. It is easy to see that $T$ is a rational surface and Pic $T$ has rank $>1$.

## $\S 2$. Reduction to the rank one case

In this section, using Kawamata's contraction theorem, we will show that it is enough to prove the main theorem when Pic $S \cong \mathbf{Z}$. (Note that since $S$ is simply-connected, Pic $S$ is isomorphic to $\mathbf{Z}$ if the rank of Pic $S$ is one.)

Suppose rank Pic $S \geq 2$. Since $K_{S}$ is not nef, there is a contraction $\varphi: S \rightarrow Y$ of an extremal ray by [10, Theorem 3.2.1]. (Note that a twodimensional quotient singularity is nothing but a log-terminal singularity (cf. [9].) We have two cases:

Case 1. $Y$ is a surface.
In this case $\varphi$ is birational and the exceptional divisor of $\varphi$ is an irreducible curve $\Delta$ (cf. [10, Prop. 5.1.6]).

Lemma 2.1. $Y$ is a log del Pezzo surface.
Proof. From [9] we know that $S$ has at worst log-terminal singularities. The proof of the Contraction Theorem shows that $Y$ also has logterminal singularities, hence quotient singularities.

Clearly, $\varphi_{*}\left(K_{S}\right)=K_{Y}$. We can write

$$
K_{S}=\varphi^{*}\left(K_{Y}\right)+a \Delta \quad \text { for some } \quad a \in \mathbf{Q}
$$

We have $K_{S} \cdot \Delta=a \Delta \cdot \Delta<0$ and $\Delta \cdot \Delta<0$ hence $a>0$. Let $Z \in$ $\overline{N E}(Y)-\{0\}$. By the projection formula,
$\left(-K_{Y}\right) \cdot Z=-\left(\varphi^{*} K_{Y}\right) \cdot \varphi^{*}(Z)=-K_{S} \cdot \varphi^{*}(Z)+a \Delta \cdot \varphi^{*}(Z)=-K_{S} \cdot \varphi^{*}(Z)>0$
by the ampleness of $-K_{S}$. Now by Kleiman's criterion of ampleness, $-K_{Y}$ is ample.

This proves that $Y$ is a $\log$ del Pezzo surface.
Now $S-\Delta \cong Y-\varphi(\Delta)$, hence $Y^{o}-\{$ one smooth point $\}$ is a Zariski-open subset of $S^{o}$. This implies that we have a surjection $\pi_{1}\left(Y^{o}\right) \rightarrow \pi_{1}\left(S^{o}\right)$.On the other hand, rank Pic $Y<\operatorname{rank}$ Pic $S$.

Case 2. $\quad Y$ is a smooth projective curve.
In this case by Lemma $1.3, Y \cong \mathbf{P}^{1}$. We claim that a general fiber of $\varphi$ is isomorphic to $\mathbf{P}^{1}$. For, if $F$ is a general fiber of $\varphi$, then $-K_{S} \cdot F>0$ and $F \cdot F=0$. Now by the adjunction formula we see that $F \cong \mathbf{P}^{1}$.

By restriction, we get a surjective morphism $S^{0} \rightarrow \mathbf{P}^{1}$ whose general fibers are $\mathbf{P}^{1}$. For any scheme-theoretic fiber $F$ of $S^{o} \rightarrow \mathbf{P}^{1}$, the g.c.d. of the multiplicities of the irreducible components of $F$ is called the multiplicity of $F$.

Let $F_{1}, F_{2}, \cdots, F_{r}$ be all the multiple fibers of $S^{o} \rightarrow \mathbf{P}^{1}$ with multiplicities $m_{1}, m_{2}, \cdots, m_{r}$ bigger than one.

Suppose first $r \geq 3$. Then by the solution of Fenchel's conjecture due to R. Fox, there is a finite Galois morphism $B \rightarrow Y$ such that for any point
in $B$ lying over $\varphi\left(F_{i}\right)$, the ramification index is $m_{i}$ (cf. [3,5]). By usual arguments, the normalization $T^{o}$ of $S^{o} \times_{Y} B$ in its function field is an étale covering of $S^{o}$. The normalization of $S$ in the function field of $T^{o}$ is therefore a $\log$ del Pezzo surface $T$ by Lemma 1.2. By Lemma 1.3, $T$ is rational and hence $B \cong \mathbf{P}^{1}$. The morphism $T^{o} \rightarrow B$ has no fibers of multiplicity> 1 and has $\mathbf{P}^{1}$ as a general fiber. Then by Lemma 1.9 we have a surjection $\pi_{1}(F) \rightarrow \pi_{1}\left(T^{o}\right)$ for a general fiber $F$ of $T^{o} \rightarrow B$.

Hence $T^{o}$ is simply connected and hence $\pi_{1}\left(S^{o}\right)$ is finite.
Suppose $r \leq 2$.
If $r=2$, let $F_{1}, F_{2}$ be the multiple fibers with multiplicities $m_{1}, m_{2}$ and $d=$ g.c.d. $\left(m_{1}, m_{2}\right)$. We consider the cyclic $d-$ fold covering $B \rightarrow Y$ ramified precisely over $\varphi\left(F_{1}\right)$ and $\varphi\left(F_{2}\right)$ with ramification index $d$. Then we work with the normalization of $S^{o} \times_{Y} B$ exactly as above and complete the proof.

In case $r=1$ we get a surjection $\pi_{1}(F) \rightarrow \pi_{1}\left(S^{0}\right)$. This follows by applying Lemma 1.9 to the fibration outside the multiple fiber.

This completes the proof of the Main Theorem when there is a MoriKawamata contraction of fiber type.

For future use, we state the following result whose proof is completely similar to the proof in Case 2 above.

Lemma 2.2. Let $Y$ be a log del Pezzo surface with a morphism $\varphi$ : $Y^{0} \rightarrow \mathbf{P}^{1}$. Assume that a general fiber of $\varphi$ is isomorphic to either $\mathbf{C}$ or $\mathbf{C}^{*}$. Then $\pi_{1}(Y-\operatorname{Sing} Y)$ is finite.

Combining the arguments in Cases 1 and 2, by a repeated application of contractions of extremal rays we reduce the proof of the main theorem to the case when Pic $S \cong \mathbf{Z}$.

## §3. Some analysis of the rank one case

In this section we give a somewhat detailed description of rank one log del Pezzo surfaces.

So let $S$ be a $\log$ del Pezzo surface of rank one. We use the notation introduced in the beginning of $\S 1$. Let $p$ be the smallest positive integer such that $p D^{*}$ is an integral divisor.Then for every curve $B$ on $\widetilde{S}$ not contained in $D,-\left(K_{\widetilde{S}}+D^{*}\right) \cdot B \in \frac{1}{p} \mathbf{N}=\{n / p \mid n \in \mathbf{N}\}$ (cf. Lemma 1.1). Here, $N$ denotes the set of non-negative integers. From this we obtain the following:

Definition and Lemma 3.1. (1) There exists an irreducible curve $C$ on $\widetilde{S}$ such that $-\left(K_{\widetilde{S}}+D^{*}\right) \cdot C$ attains the smallest positive value. Such $a$ curve satisfies $C^{2} \geq-1$ (cf. Lemma 1.1,(4)).
(2) A curve $C$ as in (1) above is called minimal.

For the time being, we fix the curve $C$ of Lemma 3.1. We shall treat the two cases $\left|K_{\widetilde{S}}+C+D\right| \neq \phi,\left|K_{\widetilde{S}}+C+D\right|=\phi$ separately.

## §3.1 The case $\left|K_{\widetilde{S}}+C+D\right| \neq \phi$

In this subsection, we always assume $\left|K_{\widetilde{S}}+C+D\right| \neq \phi$.
Lemma 3.2 (cf. [18, Lemma 2.1]). Let $C$ be as in Lemma 3.1.Suppose $\left|C+D+K_{\widetilde{S}}\right| \neq \phi$. Then there exists a unique decomposition $D=D^{\prime}+D^{\prime \prime}$ such that:
(1) $K_{\widetilde{S}}+C+D^{\prime \prime} \sim 0$,
(2) $D^{\prime}$ is disjoint from $C \cup D^{\prime \prime}$ and consists of $(-2)$-curves; hence $D^{\prime}$ is contracted to rational double points on $S$.

REmARK 3.3. Write $\widetilde{C}:=f^{*} f_{*}(C)=C+G$.As Pic $S \cong \mathbf{Z}, C+G$ is a nef and big divisor and $G$ is an effective divisor with support contained in $D^{\prime \prime}$. In particular, the Iitaka $D$-dimension $\kappa\left(\widetilde{S}, C+D^{\prime \prime}\right)=2$.

Remark 3.4. We can divide the case $\left|C+D+K_{\widetilde{S}}\right| \neq \phi$ into the following subcases:

Case (I-1) $\quad D^{\prime \prime}=0$. Then $S$ is a log del Pezzo surface with only rational double points. By Proposition 1.11, $\pi_{1}\left(S^{o}\right)$ is finite abelian.

In the following subcases, assume that $D^{\prime \prime} \neq 0$. Now from $K_{\widetilde{S}}+C+D^{\prime \prime} \sim$ 0 and by applying Lemma 1.8 to any proper subset of $C \cup D^{\prime \prime}$ we see that each irreducible component of $C \cup D^{\prime \prime}$ is isomorphic to $\mathbf{P}^{1}$.

Case (I-2) $\quad D^{\prime \prime} \neq 0$ and $C+D$ is a divisor with only simple normal crossings. By Lemmas 1.8 and 3.2, there is a loop $\Delta$ of nonsingular rational curves contained in $C+D^{\prime \prime}$ and we have $\left|K_{\widetilde{S}}+\Delta\right| \neq \phi$. Now $K_{\widetilde{S}}+C+D^{\prime \prime} \sim 0$ implies that $\Delta=C+D^{\prime \prime}$ and $C+D^{\prime \prime}$ is a simple loop of nonsingular rational curves, i.e., each irreducible curve in $C+D^{\prime \prime}$ meets exactly two other irreducible components of $C+D^{\prime \prime}$.

Case (I-3) $\quad D^{\prime \prime} \neq 0$ and $\left(C^{2}\right) \geq 0$. This case can be reduced to the case(I-2) above by replacing $C$ with a new irreducible curve linearly equivalent to $C$. Indeed, by the Riemann-Roch theorem, the Serre duality and the genus formula, we have:

$$
\operatorname{dim}|C|=h^{1}(\widetilde{S}, \mathcal{O}(C))+\frac{1}{2}\left(C, C-K_{\widetilde{S}}\right) \geq 1
$$

Then $|C|$ has no base points (as $C \cong \mathbf{P}^{1}$ and $\widetilde{S}$ is rational). Choose $C^{\prime} \in|C|$ such that $C^{\prime}+D$ has only simple normal crossings. Then $-\left(K_{\widetilde{S}}+D^{*}\right) \cdot C^{\prime}$ attains the smallest positive value and $\left|K_{\widetilde{S}}+C^{\prime}+D\right| \neq \phi$.

Case (I-4) $\quad D^{\prime \prime} \neq 0,\left(C^{2}\right) \leq-1$ and $C+D$ is not a divisor with only simple normal crossings. Then $C$ is a $(-1)$-curve by Lemma 3.1 and the arguments as in Case (I-2) shows that one of the following two cases occurs.

Case (I-4a) $\quad D^{\prime \prime}$ is an irreducible curve such that $C \cdot D^{\prime \prime}=2$ and $C \cap D^{\prime \prime}$ is a single point.By Remark 3.3, the intersection matrix of $C+D^{\prime \prime}$ has one positive eigenvalue and hence $\left(D^{\prime \prime}\right)^{2}=-2$ or -3 .

Case (I-4b) $D^{\prime \prime}$ consists of two irreducible components $D_{1}^{\prime \prime}, D_{2}^{\prime \prime}$ such that $C \cdot D_{1}^{\prime \prime}=C \cdot D_{2}^{\prime \prime}=1$ and $C \cap D_{1}^{\prime \prime} \cap D_{2}^{\prime \prime}$ consists of a single point.By the same reasoning as in Case (I-4a), we have $\left(\left(D_{1}^{\prime \prime}\right)^{2},\left(D_{2}^{\prime \prime}\right)^{2}\right)=(-2,-2)$, $(-2,-3),(-2,-4)$ after interchanging the subscripts of $D_{i}^{\prime \prime}$, if necessary.
$\S$ 3.2 The Case $\left|K_{\widetilde{S}}+C+D\right|=\phi$
In this section we always assume that $\left|K_{\widetilde{S}}+C+D\right|=\phi$. First of all, by Lemma 1.8, we have the following:

Lemma 3.5. $\quad C+D$ has only simple normal crossings, consists of nonsingular rational curves and has a disjoint union of trees as the dual graph.

We need the following results from [18].
Proposition 3.6 (cf. the proof of [18, Lemma 2.2]). Let $C$ be as in Lemma 3.1. Suppose $\left|C+D+K_{\widetilde{S}}\right|=\phi$. Then either $C$ is a $(-1)$-curve or $S$ is $\mathbf{P}^{2}$ or $S$ is the Hirzebruch surface with the minimal section contracted. In the latter cases, $S^{o}$ is simply connected.

From now on till the end of the present section, we assume always that $C$ is a ( -1 )-curve.

Lemma 3.7 (cf. [18, Lemma 4.1]). Let $D_{1}, \cdots, D_{r}$ exhaust all irreducible components of $D$ with $\left(C, D_{i}\right)>0$. Suppose $\left(D_{1}^{2}\right) \geq \cdots \geq\left(D_{r}^{2}\right)$. Then $\left\{-\left(D_{1}^{2}\right), \cdots,-\left(D_{r}^{2}\right)\right\}$ is one of the following:

$$
\left\{2^{a}, n\right\}(n \geq 2),\left\{2^{a}, 3,3\right\},\left\{2^{a}, 3,4\right\},\left\{2^{a}, 3,5\right\}
$$

where $2^{a}$ signifies that 2 is repeated a-times.
Lemma 3.8 (1) Suppose $C$ meets exactly one irreducible component $D_{0}$ of $D$. Then $\left(D_{0}^{2}\right)=-2$.
(2) $C$ meets at least one component of $D$.

Proof. (1) Suppose $\left(D_{0}^{2}\right) \leq-3$. Then $C+D$ is contractible to quotient singularities. This leads to $1+\#(D)=\rho(\widetilde{S}) \geq 1+\#(C+D)$, the last inequality holds because the intersection form on the Neron-Severi group of $\widetilde{S}$ has one positive eigenvalue. This is a contradiction.
(2) can be similarly verified.

Lemma 3.9 (cf. [18, Lemma 4.4]). Suppose C meets exactly two irreducible components $D_{0}, D_{1}$ of $D$. Then $\left(D_{i}^{2}\right)=-2$ for $i=0$ or 1 .

Lemma 3.10 (cf. [18, Lemma 4.3]). Assume that one of the following cases takes place:
(1) $C$ meets only one irreducible component $D_{0}$ of $D$.
(2) $C$ meets exactly two irreducible components $D_{0}, D_{1}$ of $D$, and $\left(D_{1}^{2}\right) \leq$ -3 .

Let $\sigma: \widetilde{S} \rightarrow \widetilde{T}$ be the blowing-down of the $(-1)$-curve $C$, let $E=$ $\sigma\left(D_{0}\right)$ and let $B=\sigma\left(D-D_{0}\right)$. Then there exists a log del Pezzo surface $T$ of Picard number one and there exists a birational morphism $g: \widetilde{T} \rightarrow T$ such that $g$ is a minimal resolution and $B=g^{-1}(\operatorname{Sing} T)$.

REMARK 3.11. Let $D_{1}, \cdots, D_{r}$ be all irreducible components of $D$ with $\left(C, D_{i}\right)>0$ (hence $\left(C, D_{i}\right)=1$ by Lemma 3.5). Suppose $\left(D_{1}^{2}\right) \geq \cdots \geq\left(D_{r}^{2}\right)$. By virtue of Lemmas 3.5, 3.7, 3.8 and 3.9, in the case where $C$ is a ( -1 )curve, we can divide into the following cases:

Case (II-1) $r \geq 2$ and $\left(D_{1}^{2}\right)=\left(D_{2}^{2}\right)=-2$.
Case (II-2) $r=1$ and $\left(D_{1}^{2}\right)=-2$.
Case (II-3) $r=3$ and $\left\{\left(D_{1}^{2}\right),\left(D_{2}^{2}\right),\left(D_{3}^{2}\right)\right\}=\{-2,-3,-3\},\{-2,-3,-4\}$ or $\{-2,-3,-5\}$.

Case (II-4) $r=2$ and $\left(D_{1}^{2}\right)=-2,\left(D_{2}^{2}\right) \leq-3$.
We shall consider these cases separately in $\S 5, \S 6$ and part II.
As remarked in the Introduction, Cases (II-3), (II-4) are " 3 -component case" and " 2 -component case" respectively.

In $\S 6$ and part II we shall be tacitly using the following useful result very often for estimating the coefficients of irreducible components in $D^{*}$. (For the proof, cf. [18, Lemma 1.7]). Write $D=\sum_{i=1}^{n} D_{i}$.

Lemma 3.12 Let $\left\{B_{1}, \cdot \cdot, B_{r}\right\}(1 \leq r \leq n)$ be a subset of $\left\{D_{1}, \cdots D_{n}\right\}$, say $B_{i}=D_{i}(1 \leq i \leq r)$. Assign formally the numbers $B_{i}^{2}$ and $B_{i} \cdot K_{\widetilde{S}}$ to $B_{i}$ so that $D_{i}^{2} \leq B_{i}^{2} \leq-2$ and $B_{i} \cdot K_{\widetilde{S}}:=-2-B_{i}^{2}$. Write $D^{*}=\sum_{i=1}^{n} \alpha_{i} D_{i}$. Define rational numbers $b_{1}, \cdots, b_{r}$ by the conditions

$$
B_{j} \cdot\left(K_{\widetilde{S}}+\Sigma_{i=1}^{r} b_{i} B_{i}\right)=0(j=1, \cdots, r)
$$

where $B_{i} \cdot B_{j}:=D_{i} \cdot D_{j}$ if $i \neq j$.
Then $\alpha_{i} \geq b_{i} \geq 0(i=1, \cdots, r)$. Taking $r=1$, we obtain $\alpha_{i} \geq 1+2 / D_{i}^{2}$.

## §4. The proof of the main theorem when $\left|K_{\widetilde{S}}+C+D\right| \neq \phi$

In this section we prove the Main Theorem stated in the introduction under the assumption that $\left|K_{\widetilde{S}}+C+D\right| \neq \phi$.

By the discussion in Remark 3.4, we need only to consider the cases (I-2), (I-4a) and (I-4b).

First we dispose of the cases (I-4a) and (I-4b).
Consider the case (I-4a). By two blowing-ups we get a smooth projective surface $X$ with a morphism $g: X \rightarrow \widetilde{S}$ such that the total transform $B$ of $C \cup D^{\prime \prime}$ is a divisor with simple normal crossings and has four irreducible components with a $(-1)$-curve $B_{0}$ meeting the three other components $B_{1}, B_{2}, B_{3}$. Further, $B_{1}^{2}=-2, B_{2}^{2}=-3, B_{3}^{2}=-4$ or -5 .

Let $U$ be a small nice tubular neighbourhood of $B_{0} \cup B_{1} \cup B_{2} \cup B_{3}$ in $X$. Then Mumford's result in [14] shows that $\pi_{1}(\partial U)$ has the following
presentation:

$$
<e_{0}, e_{1}, e_{2}, e_{3} \mid e_{1}^{2}=e_{2}^{3}=e_{3}^{\ell}=e_{0}, e_{1} e_{2} e_{3}=e_{0}>
$$

where $\ell=4$ or 5 .
It is well known that $\pi_{1}(\partial U)$ is then a finite group (cf. [2]). On the other hand, the intersection matrix of $B_{0}+B_{1}+B_{2}+B_{3}$ has one positive eigenvalue. Hence by Lemma 1.10, we have a surjection

$$
\pi_{1}\left(U-B_{0} \cup B_{1} \cup B_{2} \cup B_{3}\right) \rightarrow \pi_{1}\left(X-g^{-1}(C \cup D)\right)
$$

We have also a surjection $\pi_{1}(\widetilde{S}-C \cup D) \rightarrow \pi_{1}(\widetilde{S}-D)$. Now it follows from $\pi_{1}\left(X-g^{-1}(C \cup D)\right) \cong \pi_{1}(\widetilde{S}-C \cup D)$ that $\pi_{1}(\widetilde{S}-D)$ is finite.

The proof for the case ( $\mathrm{I}-4 \mathrm{~b}$ ) is completely similar.

Now we consider the case (I-2). Then $C+D^{\prime \prime}$ has simple normal crossings, the dual graph of $C+D^{\prime \prime}$ is a simple loop of smooth rational curves and $D^{\prime}=D-D^{\prime \prime}$ is disjoint from $C+D^{\prime \prime}$.

Let $U_{0}$ be a small nice tubular neighbourhood of $D^{\prime \prime}$ in $\widetilde{S}$ and $U_{1}$ that of $C$ in $\widetilde{S}$.

We can write $\left(U_{0}-D\right) \cap\left(U_{1}-D\right)$ as a disjoint union $N_{0} \cup N_{1}$, where each $N_{i}$ is homeomorphic to $\Delta^{*} \times \Delta$, where

$$
\Delta=\{z \in \mathbf{C}| | z \mid<1\}, \Delta^{*}=\Delta-\{0\}
$$

Let $D_{1}, D_{2}$ be the irreducible components of $D^{\prime \prime}$ meeting $C\left(D_{1}=D_{2}\right.$ in case $D^{\prime \prime}$ is irreducible). By Mumford's presentation for $\pi_{1}\left(\partial U_{0}\right)$, we see immediately that "the" loop $\gamma_{1}$ in $N_{0}$ around, say $D_{1}$ generates $\pi_{1}\left(\partial U_{0}\right)$. Similarly, the loop $\gamma_{2}$ in $N_{1}$ around $D_{2}$ generates $\pi_{1}\left(\partial U_{0}\right)$. We can assume that $\gamma_{1}$ is a small loop in $C$ around one point in $C \cap D^{\prime \prime}$ and $\gamma_{2}$ a small loop in $C$ around the other point in $C \cap D^{\prime \prime}$. In $\pi_{1}(C-D)$, we have $\gamma_{1} \cdot \gamma_{2}=1$. Further, $\pi_{1}\left(U_{1}-D\right) \cong \mathbf{Z}$ generated by $\gamma_{1}$.

Now we use Lemma 1.14.
We apply this to the space $A=\left(U_{0}-D\right) \cup\left(U_{1}-D\right)$ with $A_{0}=U_{0}-$ $D, A_{1}=U_{1}-D$. Since $D^{\prime \prime}$ is contracted to a quotient singularity on $S$, $\pi_{1}\left(U_{0}-D\right)$ is a cyclic finite group. Then $\pi_{1}\left(U_{0} \cup U_{1}-D\right)$ has the presentation:

$$
\pi_{1}\left(U_{0}-D\right) * \pi_{1}\left(U_{1}-D\right) * \mathbf{Z}(u)
$$

with relations

$$
\gamma_{1}=g_{0}, g_{0}^{n}=u^{-1} \gamma_{1}^{-1} u
$$

where $g_{0}$ is the generator of $\pi_{1}\left(U_{0}-D\right)$ given by $\gamma_{1}$ and $g_{0}^{n}$ the generator of $\pi_{1}\left(U_{0}-D\right)$ given by $\gamma_{2}$.

It follows that we have an exact sequence

$$
(1) \rightarrow \pi_{1}\left(U_{0}-D\right) \rightarrow \pi_{1}\left(U_{0} \cup U_{1}-D\right) \rightarrow \mathbf{Z} \rightarrow(1)
$$

The intersection matrix of $C+D$ has one positive eigenvalue. Hence by Lemma 1.10, we have a surjection

$$
\pi_{1}\left(U_{0} \cup U_{1}-D\right) \rightarrow \pi_{1}\left(S^{o}\right)
$$

Let $K$ be the kernel of this homomorphism. Then we get an isomorphism

$$
\pi_{1}\left(U_{0} \cup U_{1}-D\right) /\left(\pi_{1}\left(U_{0}-D\right) \cdot K\right) \cong \mathbf{Z} /(a)
$$

for some $a \geq 0$, i.e.,

$$
\pi_{1}\left(S^{o}\right) /\left(\pi_{1}\left(U_{0}-D\right) \cdot K / K\right) \cong \mathbf{Z} /(a)
$$

The group $\left(\pi_{1}\left(U_{0}-D\right) \cdot K / K\right)$ is clearly finite.
Now by Proposition 1.7, $\pi_{1}\left(S^{o}\right)$ does not have normal subgroups of arbitrarily large indices. It follows that $\pi_{1}\left(S^{o}\right)$ is finite.

## §5. The proof of the main theorem in the cases (II-1) and (II-2)

We consider the case (II-1) or (II-2) in Remark 3.11. We shall employ the notation there. First of all, we have the following Theorem 5.1 which is a consequence of $\S 4$, Theorem 5.2 below and Lemma 2.2.

Theorem 5.1. Assume the case (II-1) of Remark 3.11 takes place. Then $\pi_{1}\left(S^{o}\right)$ is a finite group.

Theorem 5.2 (cf. [18, Theorem 5.1]). Assume the case (II-1) of Remark 3.11 takes place. Then one of the following cases occurs:
(1) $S^{o}$ is affine-ruled.
(2) There is an irreducible curve $C^{\prime}$ such that $-C^{\prime} \cdot\left(K_{\widetilde{S}}+D^{*}\right)=-C$. $\left(K_{\widetilde{S}}+D^{*}\right)$ while $\left|C^{\prime}+D+K_{\widetilde{S}}\right| \neq \phi$.
(3) $C+D$ has the configuration given in [18, Picture10]. In particular, there exists a $\mathbf{P}^{1}$-fibration $\varphi=\Phi_{\left|2 C+D_{1}+D_{2}\right|}: \widetilde{S} \rightarrow \mathbf{P}^{1}$ and there are two irreducible components $D_{3}, D_{4}$ of $D$ such that $D-D_{3}-D_{4}$ are contained in fibers and $D_{3}$ and $D_{4}$ are cross-sections. Hence the restriction morphism $\varphi_{\mid S^{o}}: S^{o} \rightarrow \mathbf{P}^{1}$ is a $\mathbf{C}^{*}$-fibration.

Next we consider the case(II-2) of Remark 3.11. We employ the following notations. Let $\Delta$ be the connected component of $D$ containing $D_{1}$. Then either $\Delta$ is a linear chain, or exceptional divisor of a minimal resolution of a quotient singularity (i.e. a "fork") with a central component $R$ and three twigs $T_{i}$ 's, i.e., $\Delta=R+T_{1}+T_{2}+T_{3}$. (For the definitions of fork, twig, tip, see [20, Chapter 1]).

REmark 5.3. Denote by $d_{i}=d\left(T_{i}\right)$ the absolute value of the determinant of the intersection matrix of $T_{i}$. Suppose $d_{1} \leq d_{2} \leq d_{3}$. Then $\left\{d_{1}, d_{2}, d_{3}\right\}$ is one of the following: $\{2,2, n\},\{2,3,3\},\{2,3,4\},\{2,3,5\}$. In particular, $\sum \frac{1}{d_{i}}>1$.

Now we shall prove the following Theorem 5.4.
Theorem 5.4. Assume that the case(II-2) of Remark 3.11 takes place. Then $\pi_{1}\left(S^{o}\right)$ is a finite group.

Proof. Let $\Delta$ be the connected component of $D$ such that $C$ meets the irreducible component $D_{1}$ of $\Delta$. Let $U$ be a small tubular neighborhood of $C \cup \Delta$ in $\widetilde{S}$. As $S$ has rank $1, C+\Delta$ supports an effective divisor with strictly positive self-intersection. By Lemma 1.10 we have a surjection $\pi_{1}(U-\Delta) \rightarrow$ $\pi_{1}\left(S^{o}\right)$. We can write $U$ as a union $U_{1} \cup U_{2}$, where $U_{1}$ is a small tubular neighborhood of $\Delta$ and $U_{2}$ that of $C$. Then $U-\Delta=\left(U_{1}-\Delta\right) \cup\left(U_{2}-D_{1}\right)$ and $\left(U_{1}-\Delta\right) \cap\left(U_{2}-D_{1}\right)$ is homeomorphic to $B^{*} \times B$, where $B=\{z \in \mathbf{C}| | z \mid<1\}$ and $B^{*}=B-\{0\}$. Since $U_{2}-D_{1}$ is a disc bundle over $\mathbf{A}^{1}$, we see by VanKampen theorem that $\pi_{1}(U-\Delta)$ is a homomorphic image of $\pi_{1}\left(U_{1}-\Delta\right)$. As $\Delta$ contracts to a quotient singularity, $\pi_{1}\left(U_{1}-\Delta\right)$ is finite and hence so is $\pi_{1}\left(S^{o}\right)$.

## $\S 6$. The proof of the main theorem in the case (II-3)

In the present section, we consider the case (II-3) in Remark 3.11. So, the ( -1 )-curve $C$ meets exactly three irreducible components $D_{1}, D_{2}, D_{3}$ of
$D$ and $D_{1}^{2}=-2, D_{2}^{2}=-3, D_{3}^{2}=-3,-4,-5$. Let $\Delta_{i}(i=1,2,3)$ be the connected component of $D$ containing $D_{i}$. Since $|K+C+D|=\phi$ in our case, $C+\Delta_{1}+\Delta_{2}+\Delta_{3}$ is a tree of $\mathbf{P}^{1}$ 's(cf. Lemma 3.5).

We shall prove the following Theorem 6.1 which is a consequence of Lemma 6.5, Theorems 6.12, 6.14 and 6.15.

Theorem 6.1. Suppose that the case(II-3) in Remark 3.11 occurs. Then either $\pi_{1}\left(S^{o}\right)$ is finite or there is a minimal (-1)-curve $E$ on $\widetilde{S}$ such that Case (II-4) in Remark 3.11, with C replaced by E, takes place.

First of all, we quote the following lemma from [18, Lemma 2.3]).
Lemma 6.2. Suppose the case(II-3) occurs. Then either $G\left(:=K_{\widetilde{S}}+\right.$ $\left.2 C+D_{1}+D_{2}+D_{3}\right) \sim 0$, or there exists a $(-1)$-curve $\Gamma$ such that $G \sim \Gamma$ and $\Gamma \cap\left(C+D_{1}+D_{2}+D_{2}\right)=\phi$.

Lemma 6.3. Suppose $K_{\widetilde{S}}+2 C+D_{1}+D_{2}+D_{3} \sim 0$. Then $D_{i}$ is an isolated irreducible component of $D$ for $i=1,2$ and 3 .

Proof. Suppose to the contrary that $D_{i}$ is not an isolated irreducible component of $D$ for some $i$. Then $D_{i}$ meets an irreducible component $B_{i}$ of $D-D_{i}$. This leads to $0=B_{i} .\left(K_{\widetilde{S}}+2 C+D_{1}+D_{2}+D_{3}\right) \geq B_{i} \cdot D_{i}>0$, a contradiction.

REmARK 6.4. In fact, the converse of Lemma 6.3 is also true. Namely, assume that $D_{i}$ is isolated for $i=1,2$ and 3 . Then $G\left(:=K_{\widetilde{S}}+2 C+D_{1}+\right.$ $\left.D_{2}+D_{3}\right) \sim 0$.

Lemma 6.5. Suppose that for $i=1,2$ and $3, D_{i}$ is an isolated irreducible component of $D$, i.e., $\Delta_{i}=D_{i}$. Then $\pi_{1}\left(S^{o}\right)$ is a finite group.

Proof. We use $D_{1}^{2}=-2, D_{2}^{2}=-3, D_{3}^{2}=-3,-4$ or -5 and Lemmas 1.10 and 1.13.

In view of Lemma 6.5, we may assume, from now on till the end of the section, that $D_{i}$ is not an isolated irreducible component for $i=1,2$ or 3 . Therefore, $K_{\widetilde{S}}+2 C+D_{1}+D_{2}+D_{3} \sim \Gamma$ by Lemma 6.3.

Lemma 6.6. (1) There are no $(-n)$-curves in $D-D_{2}-D_{3}$ with $n \geq 4$ and there are at most two (-3)-curves in $D-D_{2}-D_{3}$.
(2) Each connected component of $D$ contains at most one $(-n)$-curve with $n \geq 3$. In particular, $\Delta_{i}-D_{i}$ consists of $(-2)$-curves for $i=2$ and 3 , and $\Delta_{1}$ consists of $(-2)$-curves and possibly one $(-3)$-curve.

Proof. (1) Let $B_{i}(i=1, \cdots, s)$ be all $\left(-n_{i}\right)$-curves in $D-D_{1}-D_{2}-$ $D_{3}$ with $n_{i} \geq 3$. Note that $D^{*} \geq \sum_{i}\left(n_{i}-2\right) / n_{i} B_{i}$, and by Lemma $1.1,0<$ $-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right)=1-\Gamma . D^{*} \leq 1-\sum_{i}\left(n_{i}-2\right) / n_{i} \Gamma \cdot B_{i} \leq 1-\sum_{i}\left(n_{i}-2\right) / n_{i} K_{\widetilde{S}} \cdot B_{i}$ $=1-\sum_{i}\left(n_{i}-2\right)^{2} / n_{i}$ (cf. Lemma 6.2). Then the assertion (1) follows from this observation.
(2) Let $\Delta$ be a connected component of $D$. Suppose to the contrary that $\Delta$ contains two irreducible components of self intersection number $\leq-3$. Take a linear chain $G=G_{1}+\cdots+G_{t}(t \geq 2)$ in $\Delta$ such that $G_{1}^{2} \leq$ $-3, G_{t}^{2} \leq-3, G_{i} \cdot G_{i+1}=1(i=1, \cdots, t-1)$. Then $D^{*} \geq 1 / 2 \sum_{i} G_{i}$. Note that $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-1 / 2 \sum_{i} \Gamma . G_{i}$. So, $\Gamma . \sum_{i} G_{i}=0,1$.

If $\Delta \neq \Delta_{i}$ for $i=2$ and 3 , then for $k=1$ and $t$ we have $\Gamma . G_{k} \geq K_{\widetilde{S}} . G_{k} \geq$ 1 (cf. Lemma 6.2). So, $\Gamma . \sum_{i} G_{i} \geq 2$. This is a contradiction.

Suppose $\Delta=\Delta_{i}$ for $i=2$ or 3 . We may assume that $G_{1}=D_{i}$. If $t=2$, then $\Gamma \cdot G_{2} \geq\left(K_{\widetilde{S}}+D_{i}\right) \cdot G_{2} \geq 2$, a contradiction. If $t \geq 3$, then $\Gamma .\left(G_{2}+G_{t}\right) \geq\left(K_{\widetilde{S}}+D_{i}\right) .\left(G_{2}+G_{t}\right) \geq 2$, a contradiction.

Now the following lemma follows from Lemmas 6.2 and 6.6.
Lemma 6.7. Let $B$ be an irreducible component of $D$. Then $B . \Gamma>0$ if and only if one of the following cases occurs:
(1) $B \cdot D_{i}=1$ for $i=1,2$ or $3, B^{2}=-2$ and $B \cdot \Gamma=1$.
(2) $B \cdot D_{1}=1, B^{2}=-3$ and $B \cdot \Gamma=2$.
(3) $B \leq \Delta_{1}, B \cdot D_{1}=0, B^{2}=-3$ and $B \cdot \Gamma=1$.
(4) $B$ is contained in a connected component $\Delta$ of $D$ other than $\Delta_{i}$ $(i=1,2,3), \quad B^{2}=-3, \Delta-B=0$ or consists of only $(-2)$-curves, and $B . \Gamma=1$.

LEMMA 6.8. $K_{\widetilde{S}}^{2}=2+D_{3}^{2}$.
Proof. Use Lemma 6.2.

Lemma 6.9. (1) For $i=2$ or $3, \quad \Delta_{i}$ is a linear chain with $D_{i}$ as a tip.
(2) Suppose that $D_{3}^{2} \leq-4$. Then for both $i=2$ and $3, \Delta_{i}$ is a linear chain with $D_{i}$ as a tip.
(3) Suppose that $\Delta_{i}$ is a fork for $i=2$ or 3 . Then $D_{i}$ is a tip.
(4) If $\Delta_{1}$ is a fork, then $\Delta_{1}$ consists of ( -2 )-curves.

Proof. (1) Suppose to the contrary that for both $i=2$ and 3 , either $\Delta_{i}$ is a fork or $\Delta_{i}$ is a linear chain but $D_{i}$ is not a tip. Then $D^{*} \geq 1 / 2 D_{2}+$ $1 / 2 D_{3}$. This leads to $0<-C .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-C .\left(1 / 2 D_{2}+1 / 2 D_{3}\right)=0$, a contradiction.
(2) Assume $D_{3}^{2} \leq-4$. Suppose that (2) is not true for $i=2$ (resp. $i=3$ ). Then $D^{*} \geq 1 / 2 D_{2}+1 / 2 D_{3}$ (resp. $\left.D^{*} \geq 1 / 3 D_{2}+2 / 3 D_{3}\right)$. We reach a contradiction as in (1). So, (2) is true.
(3) Suppose that $\Delta_{i}$ is a fork but $D_{i}$ is not a tip for $i=2$ or 3 . Then $D^{*} \geq 2 / 3 D_{i}+1 / 3 D_{j}$ where $\{i, j\}=\{2,3\}$ as sets. We reach a contradiction as in (1).
(4) Suppose that $\Delta_{1}$ is fork but does not consist of $(-2)$-curves. Then $\Delta_{1}$ contains a ( -3 )-curve $B$ and $\Delta_{1}-B$ consists of ( -2 )-curves (cf. Lemma 6.6). Note that $D^{*} \geq 1 / 2 B$.

Case(1) $B$ is adjacent to $D_{1}$. Then $\Gamma . B=2$ by Lemma 6.7. This leads to $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma \cdot(1 / 2 B) \leq 0$, a contradiction. So, $B$ is not adjacent to $D_{1}$.

Let $B_{1}, B_{2}, \cdots, B_{s}$ be all irreducible components of $\Delta_{1}$ adjacent to $D_{1}$. Then $\Gamma \cdot B_{i}=\Gamma . B=1$ by Lemma 6.7.

Case(2) $D_{1}$ is the central component. Then $s=3$ and $D^{*} \geq 1 / 2 B+$ $1 / 2 D_{1}+1 / 2 B_{i}+1 / 4 B_{j}+1 / 4 B_{k}$, where $\{i, j, k\}=\{1,2,3\}$ as sets and $B_{i}$ and $B$ are contained in one and the same twig of $\Delta_{1}$. This leads to $0<-\Gamma$. $\left(K_{\widetilde{S}}+\right.$ $\left.D^{*}\right) \leq 1-\Gamma .\left(1 / 2 B+1 / 2 B_{i}+1 / 4 B_{j}+1 / 4 B_{k}\right)=-1 / 2$, a contradiction. So, $D_{1}$ is not the central component of $\Delta_{1}$.

Case(3) $B$ is the central component of $\Delta_{1}$. So, $D_{1}$ is contained in a twig $T_{1}$ of $\Delta_{1}$. Let $G=G_{1}+\cdots+G_{t}(t \geq 2)$ be a linear chain in $T_{1}+B$ such that $G_{1}=D_{1}, G_{i} \cdot G_{i+1}=1(i=1, \cdots, t-1), G_{t}=B$. Then $D^{*} \geq$ $\sum_{i=1}^{t} i /(t+1) G_{i}$. Note that $G_{2}=B_{j}$ for $j=1, \cdots, s-1$ or $s$. This leads to $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(2 /(t+1) B_{j}+t /(t+1) B\right)=-1 /(t+1)$, a contradiction. So, $B$ is not the central component of $\Delta_{1}$.

Since the above cases (2) and (3) are impossible, $D_{1}$ and $B$ are all contained in twigs of $\Delta_{1}$. We shall see in the cases (4) and (5) below that this again leads to a contradiction.

Case(4) $D_{1}$ and $B$ are in one and the same twig of $\Delta_{1}$. Let $G=G_{1}+$ $\cdots+G_{t}(t \geq 2)$ be a linear chain in the twig such that $G_{1}=D_{1}, G_{i} . G_{i+1}=$ $1(i=1, \cdots, t-1), G_{t}=B$. Note that $G_{2}=B_{j}$ for $j=1, \cdots, s-1$ or $s$. If the distance from $D_{1}$ to the central component of $\Delta_{1}$ is shorter than that from $B$ to the central component, then $D^{*} \geq \sum_{i} 1 / 2 G_{i}$. This leads to $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(1 / 2 B+1 / 2 B_{j}\right)=0$, a contradiction. If the distance from $D_{1}$ to the central component of $\Delta_{1}$ is longer than that from $B$ to the central component, then $D^{*} \geq \sum_{i} i /(t+1) G_{i}$. This leads to $0<-\Gamma \cdot\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma \cdot\left(2 /(t+1) B_{j}+t /(t+1) B\right)=-1 /(t+1)$, a contradiction. So, Case(4) is impossible.

Case(5) $D_{1}$ and $B$ are contained in two different twigs $T_{1}, T_{2}$ of $\Delta_{1}$. Let $R$ be the central component of $\Delta_{1}$. Let $G=G_{1}+\cdots+G_{t}(t \geq 2)$ be a linear chain in $T_{1}+R$ such that $G_{1}=D_{1}, G_{i} \cdot G_{i+1}=1(i=1, \cdots, t-1), G_{t}=R$. Then $G_{2}=B_{j}$ for $j=1, \cdots, s-1$ or $s$.

Case(5.a) $T_{2}$ has more than two irreducible components. Then $T_{1}=D_{1}$ because $\Delta_{1}$ is contractible to a quotient singularity, and $R=B_{j}$ for $j=$ $1, \cdots, s-1$ or $s$. This leads to $D^{*} \geq 1 / 2 B+1 / 2 B_{j}+1 / 4 D_{1}$ and $0<$ $-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(1 / 2 B+1 / 2 B_{j}\right)=0$, a contradiction. So, Case(5.a) is impossible.

Case(5.b) $T_{2}=B$. Then $D^{*} \geq(t+2) /(t+6) B+\sum_{i} 2 i /(t+6) G_{i}$. This leads to $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma \cdot\left((t+2) /(t+6) B+4 /(t+6) B_{j}\right)=0$, a contradiction. So, Case(5.b) is impossible.

Case(5.c) $T_{2}=B+B^{\prime}$ where $B^{\prime}$ is adjacent to $R$. Then $t=2,3$ because $\Delta_{1}$ is contractible to a quotient singularity. Moreover, $D^{*} \geq 4 /(10-t) B+$ $(2+t) /(10-t) B^{\prime}+\sum_{i} 2 i /(10-t) G_{i}$. This implies that $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq$ $1-\Gamma .\left(4 /(10-t) B+4 /(10-t) B_{j}\right)=(2-t) /(10-t) \leq 0$, a contradiction. So, Case(5.c) is impossible.

Case(5.d) $T_{2}=B+B^{\prime}$ where $B$ is adjacent to $R$. Then we have also $D^{*} \geq(t+2) /(t+10) B^{\prime}+2(t+2) /(t+10) B+\sum_{i} 4 i /(t+10) G_{i}$. We reach $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(2(t+2) /(t+10) B+8 /(t+10) B_{j}\right)=-(t+$ $2) /(t+10)<0$, a contradiction. So, Case(5.d) is impossible.

This proves Lemma 6.9.
Lemma 6.10. Assume that $\Delta_{1}$ does not consist of $(-2)$-curves. Then for both $i=2$ and $3, \Delta_{i}$ is a linear chain with $D_{i}$ as a tip.

Proof. Suppose Lemma 6.10 is false. Then for $k=2$ or 3 , either $\Delta_{k}$
is a fork or $\Delta_{k}$ is a linear chain but $D_{k}$ is not a tip. Decompose $D^{*}$ into the form: $D^{*}=\sum_{i=1}^{3} \Delta_{i}^{*}+D^{*}$ such that Supp $\Delta_{i}^{*} \subseteq \Delta_{i}$ and Supp $D^{*} \subseteq$ $D^{\prime}:=D-\sum_{i=1}^{3} \Delta_{i}$. On the one hand, we have $0<1-\Gamma . \sum_{i} \Delta_{i}^{*}-\Gamma . D^{\prime *}$. On the other hand, we shall show that $\Gamma . \Delta_{1}^{*} \geq 1 / 2$ and $\Gamma . \Delta_{k}^{*} \geq 1 / 2$. Thus, we would reach a contradiction and therefore prove Lemma 6.10.

Let $B_{1}, \cdots, B_{s}$ be anew all irreducible components of $\Delta_{k}$ adjacent to $D_{k}$. Then $\Gamma . B_{i}=1$ (cf. Lemmas 6.6 and 6.7). If $s \geq 2$, then $\Delta_{k}^{*} \geq 1 / 2 D_{k}+$ $1 / 4 \sum_{i} B_{i}$ and $\Gamma . \Delta_{k}^{*} \geq 1 / 2$. If $s=1$ then, by the additional assumption, $\Delta_{k}$ is a fork with $D_{k}$ as a tip. Therefore, $\Delta_{k}^{*} \geq 1 / 2 D_{k}+1 / 2 B_{1}$ and $\Gamma . \Delta_{k}^{*} \geq 1 / 2$.

Let $B_{1}, \cdots, B_{s}$ be all irreducible components of $\Delta_{1}$ adjacent to $D_{1}$. If $B_{i}^{2} \leq-3$ for some $i$, then $\Delta_{1}^{*} \geq 1 / 5 D_{1}+2 / 5 B_{i}$. This leads to $\Gamma . \Delta_{1}^{*} \geq 4 / 5>$ $1 / 2$ because $B_{i}^{2}=-3$ and $\Gamma . B_{i}=2$ (cf. Lemmas 6.6 and 6.7).Suppose that $B_{i}^{2}=-2$ for all $i$. By the hypothesis, $\Delta_{1}-\sum_{i} B_{i}$ contains a $(-3)$ curve $B$ (cf. Lemma 6.6).Let $G:=G_{1}+\cdots+G_{t}(t \geq 3)$ be a linear chain in $\Delta_{1}$ such that $G_{1}=D_{1}, G_{2}=B_{1}$ and $G_{t}=B$. Then $\Delta_{1}^{*} \geq \sum_{i} i /(2 t+1) G_{i}$. This leads to $\Gamma . \Delta_{1}^{*} \geq \Gamma .\left(2 /(2 t+1) B_{1}+t /(2 t+1) B\right)=(t+2) /(2 t+1)>1 / 2$ (cf. Lemma 6.7).

This proves Lemma 6.10.

Lemma 6.11. Assume that $\Delta_{1}$ is a linear chain but $D_{1}$ is not a tip of $\Delta_{1}$. Then $\Delta_{1}$ consists of $(-2)$-curves.

Proof. Suppose Lemma 6.11 is false. Then by Lemma 6.10, $\Delta_{2}, \Delta_{3}$ are linear with $D_{2}, D_{3}$ as tips. Then $\Delta_{1}$ contains a ( -3 )-curve $B$ and $\Delta_{1}-B$ consists of ( -2 )-curves (cf. Lemma 6.6). By the hypothesis, $D_{1}$ meets two irreducible components $B_{1}, B_{2}$ of $\Delta_{1}$.

Claim(1). $B$ is not adjacent to $D_{1}$.
If $B$ is adjacent to $D_{1}$, say $B=B_{2}$, then $D^{*} \geq 3 / 7 B+2 / 7 D_{1}+1 / 7 B_{1}$. By Lemma 6.7, $\Gamma . B=2$ and $\Gamma . B_{1}=1$. This leads to $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq$ $1-\Gamma .\left(3 / 7 B+1 / 7 B_{1}\right)=0$, a contradiction. This proves Claim(1).

By Claim(1), $B_{1}^{2}=B_{2}^{2}=-2$. Let $S_{0}:=2\left(C+D_{1}\right)+B_{1}+B_{2}$ and let $\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ be the $\mathbf{P}^{1}$-fibration with $S_{0}$ as a singular fiber. Then $D_{2}$ and $D_{3}$ are 2-sections of $\varphi$. Let $S_{1}$ be an arbitray singular fiber, let $E_{i}(i=1, \cdots, s)$ be all $(-1)$-curves in $S_{1}$ and let $a_{i}$ be the coefficient of $E_{i}$ in $S_{1}$. By the minimality of $-C \cdot\left(K_{\widetilde{S}}+D^{*}\right)$ and by noting that $C$ has coefficient two in $S_{0}$, we see that $\sum_{i} a_{i}=2$ and for all $i, \quad-E_{i} .\left(K_{\widetilde{S}}+D^{*}\right)=-C .\left(K_{\widetilde{S}}+D^{*}\right)$.

Thus $S_{1}$ has one of the following two dual graphs:

$$
\begin{align*}
& (-1)-(-2)-(-2)-\cdots-(-2)-(-2)-(-2),  \tag{1}\\
& (-1)-(-2)-(-2)-\cdots-(-2)-(-2)-(-1),
\end{align*}
$$

where in the first (resp. second) graph $S_{1}$ has three or more(resp. two or more) irreducible components. So, no singular fiber contains a $(-n)$-curve with $n \geq 3$. In particular, $B$ must be adjacent to $B_{1}$ or $B_{2}$, say $B_{2}$, and $B$ is a cross-section of $\varphi$.

Claim(2). $\Delta_{1}=B_{1}+D_{1}+B_{2}+B$. In particular, $D^{*}=1 / 9 B_{1}+2 / 9 D_{1}+$ $3 / 9 B_{2}+4 / 9 B+\sum_{i=2}^{3} \Delta_{i}^{*}+D^{\prime *}$ where Supp $\Delta_{i}^{*} \subseteq \Delta_{i}$ and Supp $D^{*} \subseteq D^{\prime}:=$ $D-\sum_{i=1}^{3} \Delta_{i}$.

Claim(2) is equivalent to saying that $B_{1}$ and $B$ are tips. If $B_{1}$ is not a tip then $D^{*} \geq 2 / 11 B_{1}+3 / 11 D_{1}+4 / 11 B_{2}+5 / 11 B$. This leads to $0<$ $-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(2 / 11 B_{1}+4 / 11 B_{2}+5 / 11 B\right)=0($ cf. Lemma 6.7$)$, a contradiction.If $B$ is not a tip, then $D^{*} \geq 1 / 7 B_{1}+2 / 7 D_{1}+3 / 7 B_{2}+4 / 7 B$. This leads to $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(1 / 7 B_{1}+3 / 7 B_{2}+4 / 7 B\right)=-1 / 7$, again a contradiction. This proves Claim(2).

Claim(3). (1) For both $i=2$ and $3, \Delta_{i}$ is a linear chain with $D_{i}$ as a tip. (cf. Lemma 6.10.)
(2) For $i=2$ or $3, \quad \Delta_{i}=D_{i}$.

If for both $i=2$ and $3, \quad \Delta_{i}>D_{i}$, then $D^{*} \geq 2 / 9 D_{1}+2 / 5 D_{2}+2 / 5 D_{3}$. This leads to $0<-C .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-C .\left(2 / 9 D_{1}+2 / 5 D_{2}+2 / 5 D_{3}\right)=$ $-1 / 45<0$, a contradiction. This proves (2). Thus, Claim(3) is proved.

Since $B, D_{2}, D_{3}$ are not contained in fibers of $\varphi$ and since $\rho(S)=1$, there are two singular fibers $S_{1}, S_{2}$ of $\varphi$ each of which has the second type of the above picture. By Claim(3), both 2-sections $D_{2}$ and $D_{3}$ meet only $(-1)$-curves of $S_{i}$ for $i=1$ or 2 , say $i=1$. Let $E_{1}, E_{2}$ be two ( -1 )-curves in $S_{1}$. Note that the cross-section $B$ meets $E_{1}$ or $E_{2}$. Thus, $5=\left(B+D_{2}+\right.$ $\left.D_{3}\right) \cdot S_{1}=\left(B+D_{2}+D_{3}\right) \cdot\left(E_{1}+E_{2}\right)$. Thus, $\left(B+D_{2}+D_{3}\right) \cdot E_{k} \geq 3$ for $k=1$ or 2 . This, together with $D^{*} \geq 4 / 9 B+1 / 3 D_{2}+1 / 3 D_{3}$, implies that $0<-E_{k} \cdot\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-E_{k} \cdot\left(4 / 9 B+1 / 3 D_{2}+1 / 3 D_{3}\right) \leq 0$, a contradiction. This proves Lemma 6.11.

Now we shall prove the following

THEOREM 6.12. Suppose that either $\Delta_{1}$ is a fork, or $\Delta_{1}$ is a linear chain but $D_{1}$ is not a tip of $\Delta_{1}$. Then we reduce to the case in $\S 3.1$ with $C$ replaced by a new minimal (-1)-curve.

Proof. By the assumption, $\Delta_{1}$ consists of only ( -2 )-curves (cf. Lemmas 6.9 and 6.11). So, there are irreducible components $B_{1}, \cdots, B_{r}(r \geq 3)$ of $\Delta_{1}$ such that $B_{1}=D_{1}, B_{i} \cdot B_{i+1}=B_{r-2} \cdot B_{r}=1(i=1, \cdots, r-2)$ and $S_{0}:=2\left(C+\sum_{i=1}^{r-2} B_{i}\right)+B_{r-1}+B_{r}$ has the first type of the picture in Lemma 6.11. We see that $r=3$ if $\Delta_{1}$ is a linear chain or a fork with $D_{1}$ as the central component.

Let $\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ be the $\mathbf{P}^{1}$-fibration with $S_{0}$ as a singular fiber. Then $D_{2}$ and $D_{3}$ are 2-sections of $\varphi$. By the same reasoning as in Lemma 6.11, every singular fiber of $\varphi$ has one of two types in Lemma 6.11. Moreover, $-E .\left(K_{\widetilde{S}}+D^{*}\right)=-C .\left(K_{\widetilde{S}}+D^{*}\right)$ for every (-1)-curve $E$ in a singular fiber of $\varphi$. Let $S_{0}, S_{1}, \cdots, S_{s}\left(\right.$ resp. $\left.T_{1}, \cdots, T_{t}\right)$ be all singular fibers of the first (resp. second) type in Lemma 6.11. Then those $s+t+1$ ones are all singular fibers of $\varphi$. Let $E_{i}$ (resp. $E_{j 1}, E_{j 2}$ ) be the ( -1 )-curve(s) in $S_{i}$ (resp. $T_{j}$ ). Let $G_{i m}, H_{j n}$ be irreducible components of $D$. We can write $S_{i}, T_{j}$ in the following forms:

$$
\begin{gathered}
S_{i}=2\left(E_{i}+\sum_{k=1}^{s_{i}-2} G_{i, k}\right)+G_{i, s_{i}-1}+G_{i, s_{i}}, \\
T_{j}=E_{j 1}+\sum_{k=1}^{t_{j}} H_{j, k}+E_{j 2},
\end{gathered}
$$

where $E_{0}=C, E_{i} \cdot G_{i, 1}=G_{i, k} \cdot G_{i, k+1}=G_{i, s_{i}-2} \cdot G_{i, s_{i}}=1\left(k=1, \cdots, s_{i}-\right.$ 2), $E_{j, 1} \cdot H_{j, 1}=H_{j, k} \cdot H_{j, k+1}=H_{j, t_{j}} \cdot E_{j, 2}=1\left(k=1, \cdots, t_{j}-1\right)$.

Let $\sigma: \widetilde{S} \rightarrow \Sigma_{d}$ be a smooth blowing-down of all irreducible components in $S_{i}$ 's and $T_{j}$ 's except for $G_{i, s_{i}}$ 's and $E_{j, 2}$ 's. Here $\Sigma_{d}$ is a Hirzebruch surface of degree $d$. Let $M_{d}$ be the minimal section of $\Sigma_{d}$. Then $\sigma\left(D_{k}\right) \sim 2 M_{d}+$ $b_{k} \sigma\left(S_{0}\right)$ for $k=2,3$. In particular, $\sigma\left(D_{k}\right)^{2} \equiv \sigma\left(D_{2}\right)^{2}-\sigma\left(D_{3}\right)^{2} \equiv 0(\bmod 4)$ for $k=2,3$.

Claim(1). (1) Suppose that $D_{k} \cdot E_{j a}=0$ for some $j$ in $\{1, \cdots, t\}$, some $k$ in $\{2,3\}$ and some $a$ in $\{1,2\}$. Then we are reduced to the case in $\S 4$ with $C$ replaced by $E_{j b}$ where $\{a, b\}=\{1,2\}$ as sets.
(2) Suppose that for $k=2$ or 3 and for some $i$ in $\{1, \cdots, s\}$, we have $D_{k} \cdot E_{i}=0$ in the case $s_{i}=2$ and $D_{k} \cdot E_{i}=D_{k} \cdot G_{i, 1}=0$ in the case $s_{i} \geq 3$. Then we are reduced to the case in $\S 4$ with $C$ replaced by $E_{i}$.

By the assumption, $2=D_{k} \cdot S_{j}=D_{k} \cdot\left(S_{j}-E_{j a}\right)$.So, $E_{j b}+D$ contains a loop and $\left|K_{\widetilde{S}}+E_{j b}+D\right| \neq \phi$ (cf. Lemma 1.8). The first assertion of Claim(1) is proved.

In the case $s_{i}=2$, we have $2=D_{k} \cdot S_{i}=D_{k} \cdot\left(G_{i, 1}+G_{i, 2}\right)$. Hence $E_{i}+D$ contains a loop and the claim is proved. In the case $s_{i} \geq 3$, we have $D_{k} \cdot G_{i, n}=1$ for some $2 \leq n \leq s_{i}-2$ or $D_{k} \cdot\left(G_{i, s_{i}-1}+G_{i, s_{i}}\right)=2$ by the assumption and by $D_{k} \cdot S_{i}=2$. Then $\Delta_{k}$ can not be contracted to a quotient singularity, a contradiction.

This proves Claim(1).
By Claim(1), we may assume that for both $k=2$ and 3, we have $D_{k} \cdot E_{j 1}=D_{k} \cdot E_{j 2}=1$ for all $j$ 's, that $D_{k} \cdot E_{i}=1$ for all $i$ 's with $s_{i}=2$ and that $D_{k} \cdot\left(E_{i}+G_{i, 1}\right)=1$ for all $i$ 's with $s_{i} \geq 3$.

Case(1). $D_{k} \cdot G_{i, 1}=1$ for some $k$ in $\{2,3\}$ and some $i$ in $\{1, \cdots, s\}$ with $s_{i} \geq 3$, say $i=1$. Then $\Delta_{k}$ is a fork with $G_{1, s_{1}-2}$ as the central component. Thus, $\Delta_{k} \cdot E_{i}=1$ for all $i \neq 1$ because $\Delta_{k}$ is contractible to a quotient singularity. By Lemma $6.9, \Delta_{k^{\prime}}$ is a linear chain with $D_{k^{\prime}}$ as a tip and $D_{k}^{2}=D_{k^{\prime}}^{2}=-3$, where $\left\{k, k^{\prime}\right\}=\{2,3\}$ as sets. Hence $D_{k^{\prime}} . E_{i}=1$ for all $i$ for otherwise $\Delta_{k^{\prime}}$ would be a fork. But then $\sigma\left(D_{k}\right)^{2}=-3+\sum_{i} s_{i}+\sum_{j}\left(t_{j}+1\right)-1$ and $\sigma\left(D_{k^{\prime}}\right)^{2}=-3+\sum_{i} s_{i}+\sum_{j}\left(t_{j}+1\right)$. This contradicts $\sigma\left(D_{2}\right)^{2}-\sigma\left(D_{3}\right)^{2} \equiv 0$ $(\bmod 4)$. So, Case(1) is impossible.

Case(2) $D_{k} \cdot E_{i}=1$ for both $k=2$ and 3 and for all $i$ in $\{1, \cdots, s\}$. Then $\sigma\left(D_{k}\right)^{2}=D_{k}^{2}+\sum_{i} s_{i}+\sum_{j}\left(t_{j}+1\right)$ for both $k=2$ and 3 . Since $\sigma\left(D_{2}\right)^{2}-$ $\sigma\left(D_{3}\right)^{2} \equiv 0(\bmod 4)$, we must have $D_{2}^{2}=D_{3}^{2}=-3$. Then $\sigma\left(D_{2}\right)^{2}=\sigma\left(D_{3}\right)^{2}$. Hence $\sigma\left(D_{2}\right) \sim \sigma\left(D_{3}\right)$. Thus, $\sigma\left(D_{2}\right) \cdot \sigma\left(D_{3}\right)=\sigma\left(D_{2}\right)^{2}$. But $\sigma\left(D_{2}\right) \cdot \sigma\left(D_{3}\right)=$ $\sum_{i} s_{i}+\sum_{j}\left(t_{j}+1\right)$. We reach a contradiction. So, Case(2) is impossible.

This proves Theorem 6.12.
THEOREM 6.13. Suppose that $\Delta_{1}$ is a linear chain with $D_{1}$ as a tip. Then for both $i=2$ and $3, \quad \Delta_{i}$ is a linear chain with $D_{i}$ as a tip.

Proof. We consider, througout the proof, the case where $\Delta_{1}$ is a linear chain with $D_{1}$ as a tip and for $k=2$ or $3, \Delta_{k}$ is either a fork or a linear chain but $D_{k}$ is not a tip. We want to get a contradiction. By Lemma 6.10, $\Delta_{1}$ consists of $(-2)$-curves.By Lemma 6.9 , we have $D_{3}^{2}=-3$ and $\Delta_{k^{\prime}}$ is a
linear chain with $D_{k^{\prime}}$ as a tip, where $\left\{k^{\prime}, k\right\}=\{2,3\}$ as sets. So, we may assume that $k^{\prime}=2, k=3$ because $D_{2}^{2}=D_{3}^{2}=-3$. Let $G_{i}(1 \leq i \leq s ; s \geq 3)$ be irreducible components of $\Delta_{3}$ such that $G_{1}=D_{3}, G_{i} \cdot G_{i+1}=G_{s-2} \cdot G_{s}=$ $1(1 \leq i \leq s-2)$. If $\Delta_{3}$ is a linear chain then $s=3$, and if $\Delta_{3}$ is a fork then $s \geq 4$ because $D_{3}$ is then a tip by Lemma 6.9.

Claim(1). $D-\sum_{i=1}^{3} \Delta_{i}$ consists of ( -2 )-curves.
Suppose to the contrary that $D-\sum_{i=1}^{3} \Delta_{i}$ contains a $(-n)$-curve $B$ with $n \geq 3$. Then $B^{2}=-3$ by Lemma 6.6. Moreover, $\Delta_{2}=D_{2}$ for otherwise $D^{*} \geq 2 / 5 D_{2}+1 / 5 D_{2}^{\prime}+1 / 3 B+1 / 2\left(D_{3}+G_{2}+\cdots+G_{s-2}\right)+1 / 4 G_{s-1}+1 / 4 G_{s}$ and $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(1 / 5 D_{2}^{\prime}+1 / 3 B+1 / 2 \sum_{i=1}^{s-2} G_{i}+1 / 4 G_{s-1}+\right.$ $\left.1 / 4 G_{s}\right)=1-1 / 5-1 / 3-1 / 2=-1 / 30$ (cf. Lemma 6.7), a contradiction. Here $D_{2}^{\prime}$ is an irreducible component of $\Delta_{2}$ adjacent to $D_{2}$.

Let $R_{0}:=2\left(\Gamma+\sum_{i=2}^{s-2} G_{i}\right)+G_{s-1}+G_{s}$ and let $\psi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ be the $\mathbf{P}^{1}$-fibration with $R_{0}$ as a singular fiber. Let $R_{1}$ be the singular fiber of $\psi$ containing $C+D_{1}+D_{2}$. Then there exists a ( -1 )-curve $E$ such that $E . D_{2}=1$ and $R_{1}=2 C+D_{1}+D_{2}+E$. Note that $B$ is a 2 -section of $\psi$ because $R_{0} \cdot B=2 \Gamma \cdot B=2($ cf. Lemma 6.7$)$. Hence $2=R_{1} \cdot B=E . B$. This leads to $0<-E .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-E .\left(1 / 3 B+1 / 3 D_{2}\right)=0$ because $D^{*} \geq 1 / 3 B+1 / 3 D_{2}$. We reach a contradiction. This proves Claim(1).

Let $S_{0}:=4 C+2\left(D_{1}+G_{1}+\cdots+G_{s-2}\right)+G_{s-1}+G_{s}$. Let $\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ be the $\mathbf{P}^{1}$-fibration with $S_{0}$ as a singular fiber. Then $D_{2}$ is a 4 -section. By Claim(1), every singular fiber $S_{1}$ of $\varphi$ other than $S_{0}$ consists of ( -1 )-curves and $(-2)$ - curves. So, it is easy to see that $S_{1}$ has one of two types in Lemma 6.11. Let $S_{i}(i=1, \cdots, m)$, (resp. $T_{j}(j=1, \cdots, n)$ ) be all singular fibers of the first (resp. second) type. Then $S_{0}, S_{i}$ 's, $T_{j}$ 's are all singular fibers of $\varphi$. Let $E_{i}$ (resp. $E_{i 1}, E_{i 2}$ ) be the ( -1 )-curve(s) in $S_{i}$ (resp. $T_{j}$ ).

Claim(2). $\Delta_{2}=D_{2}$.
Suppose to the contrary that $\Delta_{2}=H_{1}+\cdots+H_{t}$ with $t \geq 2, H_{1}=$ $D_{2}, H_{i} . H_{i+1}=1(i=1, \cdots, t-1)$. Let $L_{1}$ be the singular fiber of $\varphi$ containing $H_{2}+\cdots+H_{t}$. Then $L_{1}=T_{j}$ for some $j$, say $j=1$ because $D_{2}$ is a 4section and $D_{2}$ is a tip of the linear chain $\Delta_{2}$. Then $T_{1}=E_{11}+H_{2}+$ $\cdots+H_{t}+E_{12}$ with, say $E_{11} \cdot H_{2}=E_{12} \cdot H_{t}=1$. Since $D_{2}$ is a 4-section, we have $D_{2} \cdot E_{1 k} \geq 2$ for $k=1$ or 2 . This leads to $0<-E_{1 k} \cdot\left(K_{\widetilde{S}}+D^{*}\right) \leq$ $1-E_{1 k} \cdot \sum_{i}(t+1-i) /(2 t+1) H_{i} \leq 1-2 t /(2 t+1)-1 /(2 t+1)=0$ because $D^{*}=\sum_{i=1}^{t}(t+1-i) /(2 t+1) H_{i}+$ (other terms). We reach a contradiction. This proves Claim(2).

By Claim(2), $D_{2}$ meets only (-1)-curves in singular fibers. So, $D_{2} . E_{i}=$ $D_{2} \cdot E_{j 1}=D_{2} \cdot E_{j 2}=2$ for all $i=1, \cdots, m$ and $j=1, \cdots, n$ because $-E_{i k} \cdot\left(K_{\widetilde{S}}+D^{*}\right)>0$ for $k=1,2$ and $D^{*} \geq 1 / 3 D_{2}$. Let $\sigma: \widetilde{S} \rightarrow \Sigma_{d}$ be a smooth blowing-down of curves in singular fibers. Here $\Sigma_{d}$ is a Hirzebruch surface of degree $d$. Let $M_{d}$ be a minimal section on $\Sigma_{d}$. Then we have $\sigma\left(D_{2}\right) \sim 4 M_{d}+b \sigma\left(S_{0}\right)$ and $\sigma\left(D_{2}\right)^{2} \equiv 0(\bmod 8)$. On the other hand, by the above description on the intersection of $D_{2}$ with singular fibers, we have $\sigma\left(D_{2}\right)^{2} \equiv D_{2}^{2}+2(\bmod 4)$. We reach a contradiction. This proves Theorem 6.13.

Next we prove the following Theorem 6.14.
Theorem 6.14. Assume the same hypothesis as in Theorem 6.13 and assume further that $\Delta_{1}$ is not a (-2)-chain. Then either Theorem 6.1 is true, or there is a minimal (-1)-curve $E$ such that Case (II-3) in Remark 3.11, with $C, \Delta_{i}$ replaced by $E, \widetilde{\Delta_{i}}$, is true and that $\widetilde{\Delta_{1}}$ consists of exactly two (-2)-curves. Here, $\widetilde{\Delta_{i}}$ for $i=1,2,3$ are all the connected components of $D$ meeting $E$.

Proof. In view of Lemma 6.6, $\Delta_{1}$ consists of one ( -3 )-curve and several ( -2 -curves . By Theorem 6.13, $\Delta_{i}$ is a linear chain with $D_{i}$ as a tip for $i=2$ and 3 . Let $D_{i}^{\prime}$ be the irreducible component of $D$ adjacent to $D_{i}(i=$ $1,2,3)$ if it exists. Let $D^{\prime}:=D-\sum_{i=1}^{3} \Delta_{i}$. Write $\Delta_{1}=R_{1}+\cdots+R_{r}+\cdots+R_{d}$ such that $R_{1}=D_{1}, R_{r}^{2}=-3, R_{i} . R_{i+1}=1(i=1, \cdots, d-1)$. So, $R_{2}=D_{1}^{\prime}$. We have:

$$
\begin{gathered}
D^{*}=\sum_{i=1}^{r} i(d-r+1) /(d+1+r(d-r+1)) R_{i} \\
+\sum_{i=r+1}^{d} r(d-i+1) /(d+1+r(d-r+1)) R_{i}+\Delta_{2}^{*}+\Delta_{3}^{*}+D^{\prime *}
\end{gathered}
$$

where $\operatorname{Supp} \Delta_{i}^{*} \subseteq \Delta_{i}$ and $\operatorname{Supp} D^{*} \subseteq D^{\prime}$.
Case(1). $\Delta_{i}=D_{i}$ for $i=2$ and 3 .
Before we consider the Case(1), we will make some remarks which will be used often till the end of the proof of Theorem 6.1.

We will often use a different minimal (-1)-curve $E$ instead of the original curve $C$. Let $\widetilde{D_{i}}$ be all the irreducible components of $D$ which intersect $E$ and let $\widetilde{\Delta_{i}}$ be the connected component of $D$ containing $\widetilde{D_{i}}$. By repeated
use of results in $\S 3, \S 4, \S 5$, Lemmas $6.2,6.3,6.5,6.6$ and Theorems 6.12, 6.13 we see that one of the following situations takes place:
(a) Case (II-3) in Remark 3.11, with $C, \Delta_{i}$ replaced by $E, \widetilde{\Delta_{i}}$, is true. Moreover, $\widetilde{\Delta_{i}}$ is a linear chain with $\widetilde{D_{i}}$ as a tip, $\widetilde{\Delta_{1}}$ except possibly for one $(-3)$-component, $\widetilde{\Delta_{2}}-\widetilde{D_{2}}, \widetilde{\Delta_{3}}-\widetilde{D_{3}}$ are (-2)-chains and ${\widetilde{D_{2}}}^{2}=-3,{\widetilde{D_{3}}}^{2}=$ $-3,-4,-5$.
(b) Case (II-4) in Remark 3.11, with $C, \Delta_{i}$ replaced by $E, \widetilde{\Delta_{i}}, \ldots$, is true.
(c) A case in $\S 3.1, \S 5$ or Lemma 6.3 , with $C, \Delta_{i}$ replaced by $E, \widetilde{\Delta_{i}}, \ldots$, occurs. Hence, $\pi_{1}\left(S^{0}\right)$ is finite.

To prove Theorem 6.14, we can always assume that every minimal curve $E$ fits case (a) since we do not use Theorem 6.14 to treat the remaining case (II-4) in Remark 3.11.

Consider the case where $\Delta_{i}=D_{i}$ for $i=2$ and 3. By Lemma 6.6, (1) $D^{\prime}$ contains at most one ( -3 )-curve. So, $D^{\prime}$ consists of $(-2)$-curves and possibly one ( -3 )-curve (cf. Lemma 6.6).

First assume that $r>2$.
Consider the $\mathbf{P}^{1}-$ fibration $\varphi$ with $S_{0}:=3 C+2 D_{1}+R_{2}+D_{2}$ as one of the singular fibers. Then $\Gamma$ and $R_{3}$ are cross-sections, $D_{3}$ is a $3-$ section and $D-\left(D_{3}+R_{3}\right)$ is contained in fibers.

Case(1.1). $r>2$ and $D^{\prime}$ contains a ( -3 )-curve $B$.
Consider the fiber $S_{1}$ containing $B$. Since $\Gamma \cdot R_{r}=1=\Gamma \cdot B, R_{r}$ cannot lie in $S_{1}$.Hence $S_{1}$ has a unique (-3)-curve and all other components are (-1) or ( -2 ) curves. By Lemma 1.6 of [18], the sum of the coefficients of all the $(-1)$ curves in $S_{1}$ is at least 3 . As $C$ is minimal, we see that each (-1) curve $E_{i}$ in $S_{1}$ is minimal and the sum of the coefficients of the $E_{i}$ 's is precisely 3.

Case(1.1)(1). $S_{1}$ contains a unique (-1) curve $E$. Then the multiplicity of $E$ is 3 . Since $E$ fits the Case (a) above, we have $E \cdot B=E \cdot D_{3}=E \cdot G_{1}=1$ for some (-2)-curve $G_{1}$. Hence $\widetilde{D_{1}}=G_{1}, \widetilde{D}_{2}=B, \widetilde{D}_{3}=D_{3}$. Thus, $S_{1}$ has the dual graph: $B-E-G_{1}-G_{2}$ for some (-2)-curve $G_{2}$.

Since $R_{3}$ is a cross-section of $\phi, \Delta_{1}=R_{1}+\cdots+R_{5}, r=3, G_{2}=$ $R_{4}, G_{1}=R_{5}$. Now $D^{*} \geq 1 / 3 B+\Sigma_{i=1}^{3} i / 5 R_{i}$, leading to a contradiction $0<-\Gamma \cdot\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-1 / 3-(2 / 5+3 / 5)<0$ (cf. Lemma 6.7).

Case (1.1)(2). $S_{1}$ has exactly two ( -1 ) curves $E_{1}, E_{2}$ with multiplicity of $E_{2}$ equal to 2. Now $R_{3} \cap E_{2}=\phi$. Since $E_{1}$ and $E_{2}$ fit Case (a) above, we have $E_{2} \cdot B=E_{2} \cdot D_{3}=1$ and $S_{1}$ has exactly two possible configurations:
( $\alpha$ ) $S_{1}=G-E_{2}-B-E_{1}$, where $G$ is a $(-2)$ curve. As $R_{3}$ is a crosssection of $\phi$ and $E_{1}$ has to intersect some (-2) curve, we see that $R_{3}$ is a $(-2)$ curve, $R_{3} \cdot E_{1}=1$ and hence $r>3$. But then $R_{3}$ is not a tip of $\Delta_{1}$ which intersects $E_{1}$, a contradiction.
$(\beta) d=r=3, S_{1}=(-2)-E_{2}-B_{1}-\cdots-B_{m}-E_{1}, B_{1}=B, E_{1} \cdot D_{3}=$ $E_{1} \cdot R_{3}=E_{1} \cdot B_{m}=E_{2} \cdot D_{3}=E_{2} \cdot B_{1}=1$. However, $-C \cdot\left(K_{\widetilde{S}}+D^{*}\right)=$ $-E_{2} \cdot\left(K_{\widetilde{S}}+D^{*}\right)$ implies that $m=10$. Since $K_{\widetilde{S}}^{2}+\rho(\widetilde{S})=10$, we see by Lemma 6.8 that $\rho(\widetilde{S}) \leq 13$. This is a contradiction.

Case (1.1)(3). $S_{1}$ has three $(-1)$ curves $E_{1}, E_{2}, E_{3}$. Since each $E_{i}$ fits Case (a) above, using Lemma 1.6 of [18] we can assume that $E_{2}$ meets only the curve $B$ from $S_{1}$. Again since $E_{2}$ has to meet some $(-2)$ curve, $R_{3}$ is a $(-2)$ curve meeting $E_{2}$. But again in that case $R_{3}$ is not a tip of $\widetilde{\Delta_{1}}$, a contradiction.

Case(1.2). $r>2$ and $D^{\prime}$ has only $(-2)$ curves. Hence $\Gamma \cap D^{\prime}=\phi$.
Case(1.2)(1). $r>3$.
Let $S_{1}$ be the singular fiber containing the $(-3)$ curve $R_{r}$. We consider three cases as in Case(1.1) above. We are easily reduced to considering the case when $S_{1}$ has the configuration:
$R_{r}-E-G_{1}-G_{2}$, where $E^{2}=-1, G_{1}^{2}=G_{2}^{2}=-2$. As in the assertion in Case 2, part (3) below, $\# D=7+a, D_{3}^{2}=-a$. Since $E$ fits Case (a) above, we have $E \cdot D_{3}=1$ and $r=d=4$. By taking $E$ as the minimal curve, we have the case in the statement of Theorem 6.14. Indeed, $\widetilde{\Delta_{1}}=$ $G_{1}+G_{2}, \widetilde{\Delta_{2}}=R_{1}+\cdots+R_{4}, \widetilde{\Delta_{3}}=D_{3}$.

Case(1.2)(2). $r=3$. Let $\lambda=d-r$. Then the determinant of the intersection matrix of $\Delta_{1}= \pm(4 \lambda+7)$. Now $\Gamma$ meets only $R_{2}, R_{3}$. We will apply Lemma 1.14. Let $U$ be a tubular neighborhood of $\Delta_{1} \cup \Gamma$. Let a small loop around $D_{1}$ be denoted by $\gamma$. If $\gamma_{2}, \gamma_{3}$ are small loops around $R_{2}$ and $R_{3}$ respectively, then in $\pi_{1}\left(U-\Delta_{1}\right), \gamma_{2}=\gamma^{2}, \gamma_{3}=\gamma^{3}$. Then $\pi_{1}(U-D)=<\gamma, u \mid u^{-1} \gamma^{2} u=\gamma^{-3}>$. Since $<\gamma>=<\gamma^{2}>$ as the order of $\gamma$ is $4 \lambda+7$, the group generated by $\gamma$ is normal in $\pi_{1}(U-D)$. Now the same argument as in $\S 4$ shows that $\pi_{1}\left(S^{0}\right)$ is finite.

Case(1.3). Now we are left with the case $r=2$. Again first assume that $D^{\prime}$ has a $(-3)$ curve $B$. Then $D^{*} \geq 1 / 5 R_{1}+2 / 5 R_{2}+1 / 3 B$ and $0<-\Gamma$. $\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-(4 / 5+1 / 3)<0$, a contradiction. Hence $D^{\prime}$ consists of only $(-2)$ curves and $\Gamma \cap D^{\prime}=\phi$. Now again the same argument above using Lemma 1.14 shows that $\pi_{1}\left(S^{0}\right)$ is finite.

Case(2). $\Delta_{k} \neq D_{k}$ for $k=2$ or 3 . Then the following assertions are true.
(1) $D^{\prime}$ consists of $(-2)$-curves. Hence $D^{*}=\sum_{i=1}^{3} \Delta_{i}^{*}$.
(2) $D_{3}^{2}=-3,-4$ and $r \geq 3$, i.e., $\left(D_{1}^{\prime}\right)^{2}=-2$.
(3) $7-D_{3}^{2}=\sum_{i=1}^{3} \#\left(\Delta_{i}\right)+\#\left(D^{\prime}\right)$, where $\#(\Delta)$ denotes the number of irreducible component in $\Delta$.
(4) Suppose $D_{3}^{2}=-4$. Then $D_{3} . E \leq 1$ for every $(-1)$-curve $E$.

If $D^{\prime}$ contains a $(-n)$-curve $B$ with $n \geq 3$, then $n=3$ (cf. Lemma 6.6) and $D^{*} \geq 1 / 3 B+\sum_{i=1}^{r} i /(2 r+1) R_{i}+1 / 5 D_{k}^{\prime}+2 / 5 D_{k}$. This leads to $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq 1-\Gamma .\left(1 / 3 B+\sum_{i=1}^{r} i /(2 r+1) R_{i}+1 / 5 D_{k}^{\prime}\right)=$ $1-1 / 3-(r+2) /(2 r+1)-1 / 5<0$ (cf. Lemma 6.7), a contradiction. This proves the first assertion of Case(2).

If $D_{3}^{2}=-5$, then $D^{*} \geq 1 / 5 D_{2}^{\prime}+2 / 5 D_{2}+3 / 5 D_{3}$ (resp. $D^{*} \geq 1 / 3 D_{2}+$ $\left.1 / 3 D_{3}^{\prime}+2 / 3 D_{3}\right)$ in the case $k=2$ (resp. $k=3$ ). This leads to $-C .\left(K_{\widetilde{S}}+\right.$ $\left.D^{*}\right)=1-C . D^{*} \leq 0$, a contradiction. So, $D_{3}^{2}=-3,-4$.

If $r=2$, then $D^{*} \geq 1 / 5 D_{1}+2 / 5 D_{1}^{\prime}+1 / 5 D_{k}^{\prime}+2 / 5 D_{k}$ and $0<-\Gamma .\left(K_{\widetilde{S}}+\right.$ $\left.D^{*}\right) \leq 1-\Gamma .\left(2 / 5 D_{1}^{\prime}+1 / 5 D_{k}^{\prime}\right)=0$ (cf. Lemma 6.7), a contradiction. So, $r \geq$ 3. (3) follows using Noether's equality and from the following observation: $10-\left(2+D_{3}^{2}\right)=10-K_{\widetilde{S}}^{2}=\rho(\widetilde{S})=1+\#(D)($ cf. Lemma 6.8).
(4) follows from the fact that $D^{*} \geq 1 / 2 D_{3}$ and $-E .\left(K_{\widetilde{S}}+D^{*}\right)>0$.

This proves $(1) \sim(4)$ above.
From now on until the end of the proof of Theorem 6.14 we will assume that we are in the situation of Case(2).

Claim (1). It is impossible that $\Delta_{i} \neq D_{i}$ for $i=2$ and 3.
Consider the case where $\Delta_{i} \neq D_{i}$ for $i=2$ and 3 . Then $D^{*} \geq 1 / 5 D_{2}^{\prime}+$ $2 / 5 D_{2}+1 / 5 D_{3}^{\prime}+2 / 5 D_{3}+\sum_{i=1}^{r} i /(2 r+1) R_{i}$. Note that $0<-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right) \leq$ $1-\Gamma .\left(1 / 5 D_{2}^{\prime}+1 / 5 D_{3}^{\prime}+2 /(2 r+1) R_{2}+r /(2 r+1) R_{r}\right)=1-1 / 5-1 / 5-$ $(r+2) /(2 r+1)$ (cf. Lemma 6.7). Hence, $r \geq 8$. On the other hand, by the assertion (3) in Case(2), $11 \geq 7-D_{3}^{2}=\sum_{i=1}^{3} \#\left(\Delta_{i}\right)+\#\left(D^{\prime}\right) \geq r+2+2 \geq 12$. We get a contradiction.

Therefore Claim(1) is true.
Now we have either $\Delta_{2}=D_{2}$ or $\Delta_{3}=D_{3}, D_{3}^{2}=-3$ or -4 . Further, $D^{\prime}$ has only (-2) curves by the assertions in Case(2).

Claim (2) $r>4$.
Now we may assume that $\Delta_{k} \neq D_{k}, \Delta_{k^{\prime}}=D_{k^{\prime}}$ for $\left\{k, k^{\prime}\right\}=\{2,3\}$ as sets. Write $D_{k}^{2}=-a, D_{k^{\prime}}^{2}=-b$. Then $(a, b)=(3,3),(4,3),(3,4)$.

Write $\Delta_{k}=\sum_{i=1}^{t} T_{i}$ such that $T_{1}=D_{k}, T_{i} \cdot T_{i+1}=1(i=1, \cdots, t-1)$. Then we have

$$
\begin{gathered}
D^{*}=\sum_{i=1}^{r} i(d-r+1) /(d+1+r(d-r+1)) R_{i} \\
+\sum_{i=r+1}^{d} r(d-i+1) /(d+1+r(d-r+1)) R_{i} \\
+\sum_{i=1}^{t}(a-2)(t-i+1) /((a-1) t+1) T_{i}+(b-2) / b D_{k^{\prime}}
\end{gathered}
$$

We now calculate (cf. Lemma 6.7):

$$
\begin{gathered}
-C \cdot\left(K_{\widetilde{S}}+D^{*}\right)=1-(d-r+1) /(d+1+r(d-r+1)) \\
-(a-2) t /((a-1) t+1)-(b-2) / b \\
-\Gamma \cdot\left(K_{\widetilde{S}}+D^{*}\right)=1-2(d-r+1) /(d+1+r(d-r+1)) \\
-r(d-r+1) /(d+1+r(d-r+1))-(a-2)(t-1) /((a-1) t+1)
\end{gathered}
$$

Since $-C .\left(K_{\widetilde{S}}+D^{*}\right) \leq-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right)$, we get
$(r+1)(d-r+1) /(d+1+r(d-r+1)) \leq(b-2) / b+(a-2) /((a-1) t+1)$,
and

$$
\begin{equation*}
2 / b \leq(a-2) /((a-1) t+1)+r /(d+1+r(d-r+1)) \tag{14}
\end{equation*}
$$

On the other hand, by the assertions in Case(2), one has

$$
6-D_{3}^{2}=d+t+\#\left(D^{\prime}\right)
$$

Consider the case where $(a, b)=(3,3)$. May assume $\Delta_{2}=D_{2}, D_{3}^{2}=-3$ and $\Delta_{3}=\sum_{i=1}^{t} T_{i}$. By (14), we get

$$
\begin{equation*}
7 / 15 \leq 2 / 3-1 /(2 t+1) \leq r /((d+1+r(d-r+1))<1 /(d-r+1) \tag{14.1}
\end{equation*}
$$

Hence $d-r \leq 1$. If $d-r=1$, then (14.1) implies that $7 / 15 \leq r /(3 r+2)<1 / 3$, a contradiction.

So, $d=r$. Then (14.1) implies that $7 / 15 \leq r /(2 r+1)$ and $r \geq 7$.

Consider the case where $(a, b)=(4,3)$. Then $\Delta_{2}=D_{2}, D_{3}^{2}=-4$ and $\Delta_{3}=\sum_{i=1}^{t} T_{i}$. (14) implies that

$$
\begin{equation*}
8 / 21 \leq 2 / 3-2 /(3 t+1) \leq r /(d+1+r(d-r+1))<1 /(d-r+1) \tag{14.2}
\end{equation*}
$$

Hence, $d-r \leq 1$. If $d-r=1$, then (14.2) implies that $8 / 21 \leq r /(3 r+2)<$ $1 / 3$, a contradiction.

So, $d=r$. Then (14.2) implies that $2 / 3-2 /(3 t+1) \leq r /(2 r+1)<1 / 2$ and $t=2,3$. On the other hand, $0<-C .\left(K_{\widetilde{S}}+D^{*}\right)=1-1 /(2 r+1)-$ $2 t /(3 t+1)-1 / 3 \leq 1-1 /(2 r+1)-4 / 7-1 / 3$. Hence $r \geq 5$ and $r \geq 8$ if $t=3$.

Consider the case where $(a, b)=(3,4)$. Then $\Delta_{3}=D_{3}$ with $D_{3}^{2}=-4$ and $\Delta_{2}=\sum_{i=1}^{t} T_{i}$. (14) implies that
(14.3) $3 / 10 \leq 1 / 2-1 /(2 t+1) \leq r /(d+1+r(d-r+1))<1 /(d-r+1)$.

Hence $d-r \leq 2$. If $d-r=2$, then (15.3) implies that $3 / 10 \leq r /(4 r+3)<1 / 4$, a contradiction. Thus, $d-r=0,1$.

If $d=r+1$, then $0<-C \cdot\left(K_{\widetilde{S}}+D^{*}\right)=1-2 /(3 r+2)-t /(2 t+1)-1 / 2 \leq$ $1-2 /(3 r+2)-2 / 5-1 / 2=1 / 10-2 /(3 r+2)$. Hence $r>6$ and $r>8$ if $t \geq 3$. If $d=r$, then $0<-C \cdot\left(K_{\widetilde{S}}+D^{*}\right)=1-1 /(2 r+1)-t /(2 t+1)-1 / 2 \leq$ $1-1 /(2 r+1)-2 / 5-1 / 2=1 / 10-1 /(2 r+1)$. Hence $r>4$. Thus Claim(2) is proved.

Let $S_{0}=3 C+2 D_{1}+R_{2}+D_{2}$ and $\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ the fibration as before with $S_{0}$ as one of the fibers. Recall that $r>4$ and consider the fiber $S_{1}$ containing the (-3) curve $R_{r}$. Now $D_{3}$ is a 3 -section, $R_{3}$ is a cross-section, $R_{4}+\cdots+R_{d}$ is contained in $S_{1}$. Let $E_{i}(i=1, \ldots, l)$ be $(-1)$-curves in $S_{1}$. Then each $E_{i}$ is minimal.

Since each $E_{i}$ fits Case (a) above, $E_{i} \cdot R_{r}=E_{i} \cdot D_{3}=1$. Clearly $l<4$ and if $l=3$ then $S_{1}=R_{r}+E_{1}+E_{2}+E_{3}$ and $r=4$ which is not true. Hence $l<3$. From Lemma 1.6 of [18], if $l=1$ then $r=4$. Thus $l=2$ and $S_{1}=E_{1}-R_{r}-E_{2}-(-2)$. This again means $r=4$ and Theorem 6.14 is proved.

REmARK. By using a more detailed argument we can prove the following more precise result: With the same hypothesis as in Theorem 6.13, the connected component $\Delta_{1}$ consists of only (-2) curves.

Now we can prove the following Theorem 6.15 which consists of Lemmas $6.16,6.18,6.21,6.22,6.23$ and 6.24 below.

Theorem 6.15. Assume the hypothesis as in Theorem 6.13 and assume further that $\Delta_{1}$ is a (-2)-chain. Then Theorem 6.1 is true.

Now we consider the case where $\Delta_{1}$ is a linear chain with $D_{1}$ as a tip. By Theorem 6.13, for both $i=2$ and $3, \Delta_{i}$ is a linear chain with $D_{i}$ as a tip. By Lemma 6.6, $\Delta_{1}, \Delta_{2}-D_{2}$ and $\Delta_{3}-D_{3}$ consist of only ( -2 )-curves. Write $f(C) \equiv-c K_{S}, f(\Gamma) \equiv-\gamma K_{S}$. Then $-C .\left(K_{\widetilde{S}}+D^{*}\right)=c\left(K_{\widetilde{S}}+D^{*}\right)^{2}$ and $-\Gamma \cdot\left(K_{\widetilde{S}}+D^{*}\right)=\gamma\left(K_{\widetilde{S}}+D^{*}\right)^{2}$. By the choice of $C$, we have $\gamma \geq c$. By Lemma 6.2, we have $f\left(K_{\widetilde{S}}+2 C+D_{1}+D_{2}+D_{3}\right) \equiv f(\Gamma)$ and hence $-1+2 c=\gamma \geq c$. Therefore, $c \geq 1$ and $c=1$ if and only if $\gamma=1$, if and only if $\gamma=c$. We can write $f^{*} f(C) \equiv C+D_{c}^{*}$ where $D_{c}^{*} \geq 0$ and Supp $D_{c}^{*} \subseteq D$. It is easy to see that $K_{S}+f(C) \equiv(c-1)\left(-K_{S}\right)$ and $K_{\widetilde{S}}+C+D^{*}+D_{c}^{*} \equiv P_{1}$.Here $P_{1}:=-(c-1)\left(K_{\widetilde{S}}+D^{*}\right)$ which is zero (resp.a nef and big divisor) in the case $c=1$ (resp. $c>1$ ).

Write $\Delta_{1}=\sum_{i=1}^{r} R_{i}$ such that $R_{r}=D_{1}, R_{i} . R_{i+1}=1(i=1, \cdots, r-1)$, $\Delta_{2}=\sum_{i=1}^{s} S_{i}$ such that $S_{s}=D_{2}, S_{i} \cdot S_{i+1}=1(i=1, \cdots, s-1)$ and $\Delta_{3}=$ $\sum_{i=1}^{t} T_{i}$ such that $T_{t}=D_{3}, T_{i} \cdot T_{i+1}=1(i=1, \cdots, t-1)$.

Lemma 6.16. (1) $D^{*}=\sum_{i} i /(2 s+1) S_{i}+\sum_{i}(a-2) i /((a-1) t+1) T_{i}+$ $D^{\prime *}$ where $a:=-D_{3}^{2}$ and Supp $D^{*} \subseteq D^{\prime}:=D-\sum_{i=1}^{3} \Delta_{i}$.
(2) $N:=D-D^{*}-D_{c}^{*} \geq 0$ and Supp $N=D$.
(3) $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right) \geq 0$ and $K_{\widetilde{S}}+C+D=P+N$ is the Zariski decomposition where $P:=K_{\widetilde{S}}+C+D^{*}+D_{c}^{*}$. Moreover, $P \equiv-(c-1) f^{*}\left(K_{\widetilde{S}}\right)$, and hence either $c>\gamma>1$ and $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right)=2$, or $c=\gamma=1$ and $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right)=0$.

Proof. (1) follows from that $B .\left(K_{\widetilde{S}}+D^{*}\right)=0$ for every $B \leq D$. By a similar reasoning, one obtains $D_{c}^{*}=\sum_{i} i /(r+1) R_{i}+\sum_{i} i /(2 s+1) S_{i}+$ $\sum_{i} i /((a-1) t+1) T_{i}$. So, $N=\sum_{i}(r+1-i) /(r+1) R_{i}+\sum_{i}(2(s-i)+1) /(2 s+$ 1) $S_{i}+\sum_{i}((a-1)(t-i)+1) /((a-1) t+1) T_{i}+D^{\prime}-D^{\prime *}$. Then (2) follows (cf. Lemma 1.1,(1)).
(3) Note that $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right) \geq \kappa(\widetilde{S}, P)=\kappa\left(\widetilde{S}, P_{1}\right)$ (because $\widetilde{S}$ is a rational surface $)=0($ resp. 2) if $c=1$ (resp. $c>1)$. So, $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right) \geq$ 0 . So, there is a Zariski decomposition for $K_{\widetilde{S}}+C+D$.Since $P\left(\equiv P_{1}\right)$ is nef, $N \geq 0$ and $P . N_{i}=0$ for every irreducible component $N_{i}$ of $D$, the
decomposition given in (2) above is the Zariski decomposition.Therefore, $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right)=\kappa(\widetilde{S}, P)=0,2$.

This proves Lemma 6.16.
Remark 6.17. Note that every twig of $C+D$ is admissible. Since Supp $N=D \subseteq C+D, \quad N=B k^{*}(C+D)$ by Fujita [6, 6.17 and 6.18]. In particular, if $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right)=0$, then $P \equiv P_{1}=0, \quad K_{\widetilde{S}}+C+D \equiv N=$ $B k^{*}(C+D)$ and hence $\left(K_{\widetilde{S}}+C+D\right) \cdot C=B k^{*}(C+D) . C$.

Lemma 6.18. Assume $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right)=0$. Then Theorem 6.1 is true.

Proof. Let $D^{\prime}:=D-\sum_{i=1}^{3} \Delta_{i}$. By Remark 6.17, we can apply Fujita $[6,8.7]$ to the pair $(\widetilde{S}, C+D)$. Since in our case $\beta(C)=3, D_{i}^{2} \leq-3$ and $D_{i} . C=1$ for both $i=2$ and 3 , only the case(4) there takes place. Therefore, $\sum_{i=1}^{3} d\left(\Delta_{i}\right)=1$. This, together with $D_{2}^{2}=-3, D_{3}^{2}=-3,-4,-5$, implies that $D_{3}^{2}=-3, \Delta_{2}=D_{2}, \Delta_{3}=D_{3}, \Delta_{1}=D_{1}+R_{1}$ where $R_{1}$ is a ( -2 -curve. By Lemma 6.7, $. \sum_{i=1}^{3} \Delta_{i}=\Gamma . R_{1}=1$. Moreover, $D^{*}=$ $1 / 3 D_{2}+1 / 3 D_{3}+D^{\prime *}$, where Supp $D^{\prime *} \subseteq D^{\prime}$. Hence C. $D^{*}=2 / 3$.

By Lemma 6.16, $\gamma=c=1$. Hence $-\Gamma \cdot\left(K_{\widetilde{S}}+D^{*}\right)=-C \cdot\left(K_{\widetilde{S}}+D^{*}\right), \Gamma$. $D^{*}=C \cdot D^{*}=2 / 3>0$ and $\Gamma$ is a minimal curve.

By the arguments at the beginning of Theorem 6.14 , we may assume that $\Gamma$ fits Case (a) there. So $\Gamma$ meets two ( -3 )-curves $B_{1}, B_{2}$ of $D^{\prime}$.

Suppose first that $B_{1}, B_{2}$ are not both isolated components of $D$. This will lead to $\Gamma . D^{*}=\Gamma . D^{* *}>1 / 3+1 / 3$ because at least one of the connected components which contains $B_{1}$ or $B_{2}$ has more than two irreducible components. This is a contradiction.

Now we assume that both $B_{1}, B_{2}$ are isolated. We consider again the fibration $\varphi$ given by $S_{0}:=3 C+2 D_{1}+R_{1}+D_{2}$. The curve $\Gamma$ is a section of this fibration and $B_{1}, B_{2}$ lie in different singular fibers, say $S_{1}, S_{2}$ respectively. Since $\rho(\widetilde{S})=\#(D)+1, S_{i}$ contains only one (-1)-curve $E_{i}$ which is also minimal (cf. [18, Lemma 1.6]). We may assume that each $E_{i}$ fits Case (a) in Theorem 6.14. So we reduce to the situation (cf. Theorem 6.14):
$S_{1}=B_{1}-E_{1}-G_{1}-G_{2}, S_{2}=B_{2}-E_{2}-G_{3}-G_{4}$ where $G_{j}^{2}=-2$ for $j=1,2,3,4$.

The 3 -section $D_{3}$ meets only the ( -1 ) curves from the three singular fibers. The triple cover $\varphi: D_{3} \rightarrow \mathbf{P}^{1}$ has at least 3 ramification points
with ramification index 3 . This clearly contradicts Hurwitz formula.This completes the proof of Lemma 6.18.

REmark. $\quad \kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right)=0$ is impossible.
Now we consider, till the end of the proof for Theorem 6.15, the case $\kappa\left(\widetilde{S}, K_{\widetilde{S}}+C+D\right)=2$.

LEMMA 6.19. $\Delta_{4}:=D-\sum_{i=1}^{3} \Delta_{i}$ is zero or a single connected component of $D$.

Proof. We will need the following result from [7].
'Let $V$ be an affine surface with atmost quotient singularities. Assume that $H_{0}(V ; \mathbf{Q}) \approx \mathbf{Q}$ and $H_{i}(V ; \mathbf{Q})=(0)$ for $i>0$. If $\bar{\kappa}(V-\operatorname{Sing} V)=2$, then $V$ does not contain any irreducible curve homeomorphic to $\mathbf{C}$ and $V$ has at most one singular point.' (In [7], the assertion about $V$ having at most one singular point is not made but it follows very easily from the Lemma 8 of [7], as the second inequality of that lemma cannot hold if there are more than one singular points.)

To apply this, we notice that $V=S-f(C)$ satisfies the hypothesis in the result above. Hence $\Delta_{4}$ is connected.

LEMmA 6.20. (1) $\Delta_{4}=D-\sum_{i=1}^{3} \Delta_{i}$ is a single connected component of $D$ and consists of one $(-3)$-curve $B$ and several ( -2 )-curves.
(2) Write $D^{*}=\alpha B+\sum_{i} i /(2 s+1) S_{i}+\sum_{i}(a-2) i /((a-1) t+1) T_{i}+$ (other terms) in notations of Lemma 6.16. Then $1>s /(2 s+1)+(a-$ $2) t /((a-1) t+1)$ and $\alpha<1 /(2 s+1)+(a-2) /((a-1) t+1)$.
(3) $r+s+t+u=7-D_{3}^{2}$ where $r, s, t, u$ are respectively the numbers of irreducible components in $\Delta_{i}(i=1,2,3,4)$.

Proof. (1) In view of Lemmas 6.6 and 6.19 , it suffices to show the assertion that $\Delta_{4}$ contains a $(-3)$-curve. Suppose to the contrary that this assertion is false. Then $D-\left(D_{2}+D_{3}\right)$ consists of $(-2)$-curves (cf. Lemma 6.6 and Theorem 6.14). By Lemma 6.8, we have $K_{\widetilde{S}}^{2}=2-a$ where $a:=-D_{3}^{2}$. Write $D^{*}=\alpha D_{2}+\beta D_{3}+$ (other terms). First one has $0<-C .\left(K_{\widetilde{S}}+D^{*}\right)=1-\alpha-\beta$. So, one can calculate as follows:
$0<\left(K_{\widetilde{S}}+D^{*}\right)^{2}=K_{\widetilde{S}} .\left(K_{\widetilde{S}}+D^{*}\right)=K_{\widetilde{S}}^{2}+\alpha+(a-2) \beta=2-a+\alpha+(a-2) \beta$

$$
=(2-a)+(\alpha+\beta)+(a-3) \beta<(3-a)+(a-3) \beta=(a-3)(\beta-1) \leq 0
$$

We reach a contradiction. So, $\Delta_{4}$ contains a ( -3 )-curve. Thus, (1) is proved.
(2) First $0<-C .\left(K_{\widetilde{S}}+D^{*}\right)=1-s /(2 s+1)-(a-2) t /((a-1) t+1)$. So, the first inequality follows. Next, by (1) and Lemma 6.7, $-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right)=$ $1-\Gamma .\left(\alpha B+(s-1) /(2 s+1) S_{s-1}+(a-2)(t-1) /((a-1) t+1) T_{t-1}\right.$. Now the second inequality in (2) follows from that $-C .\left(K_{\widetilde{S}}+D^{*}\right)=c\left(K_{\widetilde{S}}+D^{*}\right)^{2}<$ $\gamma\left(K_{\widetilde{S}}+D^{*}\right)^{2}=-\Gamma .\left(K_{\widetilde{S}}+D^{*}\right)$.
(3) By Lemma 6.8, $K_{\widetilde{S}}^{2}=2+D_{3}^{2}$. Hence $\rho(\widetilde{S})=8-D_{3}^{2}$. Now (3) follows from that the number of irreducible components in $D$ is equal to $\rho(\widetilde{S})-1$.

We have proved Lemma 6.20.
Lemma 6.21. It is impossible that $\Delta_{i}=D_{i}$ for two of $i$ 's in $\{1,2,3\}$. In particular, $D_{3}^{2}=-3,-4$.

Proof. Assume that $\Delta_{i}=D_{i}, \Delta_{j}=D_{j}$ for some distinct $i, j$ in $\{1$, $2,3\}$. Then $\Gamma \cdot\left(\Delta_{1}+\Delta_{2}+\Delta_{3}\right) \leq 1$ and $\Gamma \cdot \Delta_{4}=1$ by Lemma 6.20(1). From the proof of Lemma 6.19, we know that $S-f(C)$ does not contain any curve homeomorphic to $\mathbf{C}$. But the image of $\Gamma$ in $S$ gives rise to such a curve. This is a contradiction.

Suppose that $D_{3}^{2}=-5$. By the first assertion $D_{2}<\Delta_{2}$ or $D_{3}<\Delta_{3}$. This leads to $D^{*} \geq 2 / 5 D_{2}+3 / 5 D_{3}$ or $D^{*} \geq 1 / 3 D_{2}+2 / 3 D_{3}$. Any of the two cases leads to $-C \cdot\left(K_{\widetilde{S}}+D^{*}\right) \leq 0$, a contradiction. So, $D_{3}^{2}=-3,-4$.

This proves Lemma 6.21.

Lemma 6.22. Suppose that $D_{3}^{2}=-4$. Then either Theorem 6.1 is true or there is a $\mathbf{P}^{1}$-fibration $\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ such that all singular fibers and irreducible components of $D$ are as described in the proof of Claim (2) below.

Proof. Consider the case $D_{3}^{2}=-4$. We use the notations in Lemmas 6.16 and 6.20. We also let $D_{1}^{\prime}=R_{r-1}, D_{2}^{\prime}=S_{s-1}, D_{3}^{\prime}=T_{t-1}$. These are $(-2)$-curves and adjacent to $D_{1}, D_{2}, D_{3}$ respectively.By the first inequality in Lemma 6.20,(2), we obtain the following:

Claim $(1) .(s, t)=(2,2),(1, t),(s, 1)$.
Consider first the case $(s, t)=(2,2)$. Then, one has $\Delta_{i}=D_{i}+D_{i}^{\prime}$ for $i=2$ and 3. By Lemma 6.20 , one has $\alpha<1 / 5+2 / 7<1 / 2$. Hence $\Delta_{4}$ is
a linear chain with $B$ as a tip. Write $\Delta_{4}=\sum_{i=1}^{u} B_{i}$ such that $B_{i} \cdot B_{i+1}=1$ and $B_{u}=B$. By the same lemma, one has $r+u=7$.

Claim(2). Suppose that $(s, t)=(2,2)$ and $r=1$. Then there is a minimal (-1)-curve $E_{2}$ on $\widetilde{S}$ and two connected components $\Delta_{3}, \Delta_{4}$ of $D$, both linear chains, $\Delta_{3}=D_{3}+D_{3}^{\prime}, \Delta_{4}=B_{1}+\cdots+B_{6}$ such that $D_{3}^{2}=-4, B_{6}^{2}=$ $-3, D_{3}^{\prime 2}=-2=B_{1}^{2}=\cdots=B_{5}^{2}$. Further, $E_{2} \cdot \Delta_{3}=E_{2} \cdot D_{3}=E_{2} \cdot \Delta_{4}=$ $E_{2} \cdot B_{5}=1$.

Consider the case where $(s, t)=(2,2)$ and $r=1$.In the present case, we have $\Delta_{1}=D_{1}$ and $u=6$. Hence

$$
\Delta_{i}(i=1,2,3,4)
$$

are all connected components of $D$. Then $\Gamma \cdot D=\Gamma .\left(B+D_{2}^{\prime}+D_{3}^{\prime}\right)=3(\mathrm{cf}$. Lemma 6.7).

Let

$$
\begin{gathered}
F_{0}:=2 \Gamma+D_{2}^{\prime}+D_{3}^{\prime} \\
\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}
\end{gathered}
$$

the $\mathbf{P}^{1}$-fibration with $F_{0}$ as a singular fiber. Let $F_{1}$ (resp. $F_{2}$ ) be the singular fiber containing $C+D_{1}$ (resp. $B_{1}+\cdots+B_{5}$ ). Then there exists a $(-1)$-curve $E$ such that $E \cdot D_{1}=1, E \cdot B_{6}=2$ and

$$
F_{1}=C+D_{1}+E
$$

because $B_{6}$ is a 2 -section. Note that $F_{2}$ consists of only $(-1)$ and $(-2)$ curves (cf. Lemma 1.1,(4)). So, $F_{2}$ has the second type in Lemma 6.11. Thus, there are two ( -1 )-curves $E_{1}, E_{2}$ such that $E_{1} \cdot B_{1}=B_{5} \cdot E_{2}=1$ and

$$
F_{2}=E_{1}+B_{1}+\cdots+B_{5}+E_{2}
$$

Since $\rho(S)=1$ and since $D-\left(D_{2}+D_{3}+B_{6}\right)$ is contained in singular fibers of $\varphi$,

$$
F_{0}, F_{1}, F_{2}
$$

are all singular fibers of $\varphi$ for otherwise the cross-section $D_{2}$ would meet an irreducible component of $D$ in a singular fiber $\left(\neq F_{0}, F_{1}, F_{2}\right)$ which contains only one ( -1 )-curve.

Let $\tau: \widetilde{S} \rightarrow \Sigma_{3}$ be a smooth blowing-down of curves in singualr fibers such that $\tau\left(D_{2}\right)^{2}=-3$. Then $\tau\left(D_{3}\right) \sim \tau\left(D_{2}\right)+3 \tau\left(F_{0}\right), \tau\left(B_{6}\right) \sim 2 \tau\left(D_{2}\right)+$
$6 \tau\left(F_{0}\right)$. Hence $\tau\left(D_{3}\right)^{2}=3$ and $\tau\left(B_{6}\right)^{2}=12$. Thus, $D_{2} \cdot E_{1}=D_{3} \cdot E_{2}=$ $B_{6} . E_{1}=1$.

Now all singular fibers of $\varphi$ and $C+D$ are precisely described above.
This proves Claim(2).
Now we have only to consider the case $r \geq 2$. Indeed, if $(s, t)=(1, t)$ or $(s, 1)$ then $r \geq 2$ by Lemma 6.21.

Claim(3). It is impossible that $(s, t)=(2,2)$ and $r \geq 2$.
We consider the case where $(s, t)=(2,2), r \geq 2$. Then $u=7-r \leq 5$. Let $F_{0}:=3 C+2 D_{1}+D_{1}^{\prime}+D_{2}$ and let $\psi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ be the $\mathbf{P}^{1}$-fibration with $F_{0}$ as a singular fiber. Since $\Gamma$ is a cross- section of $\psi$ with $\Gamma . D_{3}^{\prime}=\Gamma . B=1$, $D_{3}^{\prime}$ and $\Delta_{4}$ are contained in two distinct singular fibers, say $F_{1}, F_{2}$. So, $F_{1}$ consists of $(-1)$ and ( -2 -curves (cf. Lemma 1.1,(4)). Hence $F_{1}$ has one of two types in Lemma 6.11. Since $D_{2}^{\prime}$ is a cross-section, $F_{1}$ has two ( -1 )curves $E_{1}, E_{2}$ such that $F_{1}=E_{1}+D_{3}^{\prime}+E_{2}$ and $D_{2}^{\prime} . E_{1}=1$. Since $D_{3}$ is a 3 -section, one has $D_{3} \cdot E_{1}=D_{3} \cdot E_{2}=1$ or $D_{3} \cdot E_{i}=2$ for $i=1$ or 2 . This is a contradiction to the fact that $-E_{i} \cdot\left(K_{\widetilde{S}}+D^{*}\right)>0$. Indeed, note that $D^{*}=4 / 7 D_{3}+2 / 7 D_{3}^{\prime}+1 / 5 D_{2}^{\prime}+$ (other terms).

This proves Claim(3).
Next we consider the case where one of $s, t$ is equal to 1 . In view of Lemma 6.21, we have $r \geq 2$ and that only one of $s, t$ is equal to 1 . By Lemma 6.20, $\Delta_{4}$ has a (-3) curve $B$. Let $F_{0}:=3 C+2 D_{1}+D_{1}^{\prime}+D_{2}$ and let $\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ be the $\mathbf{P}^{1}$-fibration with $F_{0}$ as a singular fiber and $F_{1}$ the singular fiber containing $B$. By the arguments in Theorem 6.14, we may assume that every (-1)-curve $E_{i}$ in $F_{1}$ fits Case (a) there. In particular, $E_{i} \cdot B=E_{i} \cdot D_{3}=E_{i} \cdot H=1$, where $H$ is a (-2)-curve. Thus, $D_{3}$ meets only $E_{i}^{\prime} \mathrm{s}$ in $F_{1}$ because $D_{3} \cdot F_{1}=3$ (cf. [18, Lemma 1.6]).

Case(1) There are three (-1) curves $E_{1}, E_{2}, E_{3}$ in $F_{1}$. Then $F_{1}=B+\Sigma E_{i}$. There are at most 2 more horizontal irreducible components of $D$ viz. $D_{2}^{\prime}$ and $R_{r-2}$ and they are sections of $\varphi$. Hence for at least one $E_{i}, E_{i}$ meets no (-2)-curve, a contradiction.

Case(2) There are two (-1) curves $E_{1}, E_{2}$ in $F_{1}$.
Then $F_{1}$ has dual graph $E_{1}-B-E_{2}-G$, where $G$ is a (-2) curve lying in $\Delta_{1}$ or $\Delta_{2}$. If $G<\Delta_{1}$, then the section $R_{r-2}$ does not meet either of $E_{1}, E_{2}$. Since $E_{1}$ meets a (-2)-curve, $D_{2}^{\prime}$ exists and $D_{2}^{\prime} \cdot E_{1}=1$. Taking $E_{1}$ as a minimal curve we have a situation treated in the proof of Theorem 6.14. Hence Theorem 6.1 is true because in the present case $D$ has no connected
component of two (-2)-curves.
Suppose now that $G<\Delta_{2}$. Then the section $D_{2}^{\prime}$ does not meet either of $E_{1}, E_{2}$. By the same reasoning as in the case $G<\Delta_{1}$, but with $E_{1}$ replaced by $E_{2}$, Theorem 6.1 is true.

Case(3) There is a unique ( -1 ) curve $E$ in $F_{1}$.
Since $E$ fits Case (a) in Theorem 6.14, $F_{1}$ has the configuration : $B-$ $E-G_{1}-G_{2}$, where $G_{1}, G_{2}$ are (-2) curves. Now if $G_{1}+G_{2}<\Delta_{2}$, then we see using Theorem 6.14 that $r=2, s=4, t=1, u=1$ (as in this case $\Delta_{1}$ is the unique connected component of $D$ consisting of only (-2)-curves). But this contradicts Lemma 6.20, part (3). So assume $G_{1}+G_{2}<\Delta_{1}$. Now $D_{2}^{\prime}$ cannot exist as it cannot meet any curve in $F_{1}$. Hence $s=1, r=5, u=1, t=4$ by Lemma 6.20.

Since $\rho(S)=1$, the number of horizontal irreducible components of $D$ is one more than the difference between the number of $(-1)$-curves in singular fibers and the number of singular fibers of $\varphi$ (cf. Lemma 1.5 of [18]).

Now $\Gamma$ is a section of $\varphi$ and $\Delta_{3}-D_{3}$ is contained in a singular fiber, say $F_{2}$, which consists of only ( -1 ) and ( -2 ) curves. So, $F_{2}$ has the second type in Lemma 6.11 because $R_{3} \cdot F_{2}=1$.

Then every singular fiber other than $F_{2}$ has exactly one ( -1 )- curve for $\rho(S)=1$. We can write $F_{2}=E_{1}+T_{1}+T_{2}+T_{3}+E_{2}$ with two ( -1 )-curves $E_{1}, E_{2}$ such that $E_{1} \cdot T_{1}=T_{3} \cdot E_{2}=1$. Now $D^{*}=1 / 3 D_{2}+\sum_{i=1}^{4} 2 i / 13 T_{i}+$ $1 / 3 B$. Since $D_{3} \cdot F_{2}=3,\left(D_{3} \cdot E_{1}, D_{3} \cdot E_{2}\right)=(1,1),(0,2)$ or $(2,0)$. This contradicts $-E_{i} \cdot\left(K_{\widetilde{S}}+D^{*}\right)>0$. This completes the proof of Lemma 6.22.

Lemma 6.23. Suppose that $D_{3}^{2}=-3$. Then Theorem 6.1 is true.
Proof. We use the notations in Lemmas 6.16 and 6.20. We also let $D_{1}^{\prime}=R_{r-1}, D_{2}^{\prime}=S_{s-1}, D_{3}^{\prime}=T_{t-1}$. One may assume that $s \leq t$. By Lemma 6.21 , it is impossible that $(s, t)=(1,1)$. So, $t \geq 2$.

Consider first the case where $\Delta_{4}$ is a fork or a linear chain but $B$ is not a tip. Then $\alpha \geq 1 / 2$. So,

$$
1 / 2 \leq \alpha<1 /(2 s+1)+1 /(2 t+1)
$$

by Lemma 6.20 and hence $(s, t)=(1,2)$. By Lemma 6.21 we have $r>1$.
We use arguments after Claim (3) in Lemma 6.22. In that proof we have used $D_{3}^{2}=-4$ only in the last part. In the present situation, by Lemma
$6.20(3), r+s+t+u=7-(-3)=10$. The arguments in the above lemma reduced to considering the case $r=5, s=1, u=1$. But then in the present situation $t=3$, contradicting the assumption $t=2$ above. Hence the case when $\Delta_{4}$ is a fork or a linear chain but $B$ is not a tip can not occur.

Next we consider the case where $\Delta_{4}$ is a linear chain with $B$ as a tip. Write $\Delta_{4}=\sum_{i=1}^{u} B_{i}$ such that $B_{u}=B$. Then

$$
D^{*}=\sum_{i} i /(2 u+1) B_{i}+(\text { other terms })
$$

By Lemma 6.20, one has

$$
u /(2 u+1)<1 /(2 s+1)+1 /(2 t+1)
$$

Therefore, by virtue of Lemma 6.20,(3),

$$
(r, s, t, u)=(r, 1, t, 9-r-t),(5,2,2,1),(4,2,3,1)
$$

because $s \leq t$ by the additional assumption. If $r=1$ or $t=1$ then $(r, s, t, u)$ $=(r, 1, t, u)$, a contradiction to Lemma 6.21. So, $r \geq 2, t \geq 2$.

Once $r>1$, we obtain $r=5, s=1, u=1$ and hence $t=3$ by the arguments after Claim (3) in Lemma 6.22. Let $F_{0}:=3 C+2 D_{1}+D_{1}^{\prime}+D_{2}$, and $\varphi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ the $\mathbf{P}^{1}$-fibration with $F_{0}$ as a singular fiber. Then $D_{3}$ is a 3 -section. Let $F_{1}$ be the singular fiber containing $\Delta_{4}$. By the same reasoning as in Lemma 6.22, we deduce that $F_{1}=3 E+B+2 R_{1}+R_{2}$, where $E$ is a minimal (-1) curve and $E \cdot B=E \cdot R_{1}=E \cdot D_{3}=1$. We also see easily that $\varphi$ has precisely one more singular fiber $F_{2}=E_{1}+T_{1}+T_{2}+E_{2}$, where $E_{1}, E_{2}$ are (-1) curves (cf. [18, Lemma 1.5] and Lemma 1.1 (4)).

Now $D^{*}=1 / 3 D_{2}+\sum_{i=1}^{3} i / 7 T_{i}+1 / 3 B$. Since $-E_{i} .\left(K_{\widetilde{S}}+D^{*}\right)>0, D_{3} \cdot E_{i}$ $=1$ for $i=1$ and 2 because $D_{3} \cdot F_{2}=3$.

Let $S_{0}^{\prime}:=3 C+2 D_{1}+D_{1}^{\prime}+D_{3}$ and let $\psi: \widetilde{S} \rightarrow \mathbf{P}^{1}$ be the $\mathbf{P}^{1}$-fibration with $S_{0}^{\prime}$ as a singular fiber. Then $D_{2}, D_{3}^{\prime}, R_{3}$ are 3 -section, cross-section, crosssection, respectively. Since $\rho(S)=1$ and since $D_{3}^{\prime}$ is a cross-section, one can find $(-1)$-curves $L_{1}, \cdots, L_{4}$ such that $S_{0}^{\prime}, S_{1}^{\prime}:=2 L_{1}+T_{1}+B+L_{2}, S_{2}^{\prime}:=L_{3}+$ $R_{1}+R_{2}+L_{4}$ are all singular fibers of $\psi$. Moreover, $L_{1} \cdot T_{1}=L_{1} \cdot B=L_{2} \cdot B=$ $L_{2} \cdot R_{3}=L_{3} \cdot R_{1}=L_{4} \cdot R_{2}=\left(L_{3}+L_{4}\right) \cdot D_{3}^{\prime}=1$ and $\left(D_{2} \cdot L_{1}, D_{2} \cdot L_{2}\right)=(1,1)$ or $(0,3)$.

If $\left(D_{2} \cdot L_{1}, D_{2} \cdot L_{2}\right)=(1,1)$, then $-C \cdot\left(K_{\widetilde{S}}+D^{*}\right)=1-C \cdot\left(1 / 3 D_{2}+\right.$ $\left.3 / 7 D_{3}\right)=1-(1 / 3+3 / 7)>1-(1 / 3+1 / 3+1 / 7)=1-L_{1} \cdot\left(1 / 3 D_{2}+\right.$
$\left.1 / 3 B+1 / 7 T_{1}\right)=-L_{1} \cdot\left(K_{\widetilde{S}}+D^{*}\right)$, a contradiction to the choice of $C$. If $\left(D_{2} \cdot L_{1}, D_{2} \cdot L_{2}\right)=(0,3)$, then $0<-L_{2} \cdot\left(K_{\widetilde{S}}+D^{*}\right)=1-L_{2} \cdot\left(1 / 3 D_{2}+1 / 3 B\right)=$ $1-(1 / 3) \times 3-1 / 3<0$, a contradiction.

So this case is impossible. As we are using the arguments in the proof of Lemma 6.14 (i.e. we may have chosen a different minimal ( -1 )-curve in the proof above), we conclude that Theorem 6.1 is true.

This completes the proof of Lemma 6.23.
Lemma 6.24 If $\widetilde{S}$ has the $\mathbf{P}^{1}$-fibration as specified in the statement Lemma 6.22, then $\pi_{1}\left(S^{0}\right)$ is finite.

Proof. Recall that in this case the curve $E_{2}$ meets only the irreducible components $D_{3}$ and $B_{5}$ of $D$, tranversally in one point and $\Delta_{4}$ is linear with the ( -3 ) curve $B_{6}$ as a tip. Hence, $A:=E_{2}+\Delta_{4}$ supports a divisor with positive self-intersection. We will now apply Lemma 1.10.

Let $U$ be a nice tubular neighborhood of $A$. Since $E_{2}-D$ is isomorphic to $\mathbf{C}^{*}$, we see easily that $U-D$ deforms to a tubular neighborhood of $\Delta_{4}$. In particular, $\pi_{1}(U-D)$ is a finite cyclic group. By Lemma 1.10 we have a surjection of this group onto $\pi_{1}\left(S^{0}\right)$. Hence the latter group is finite.

This completes the proof of Lemma 6.24.
In view of the results in this part $\mathbf{I}$ of the paper, the proof of the Main Theorem will be complete once we have shown the finiteness of $\pi_{1}\left(S^{0}\right)$ in the "2-component" case i.e., Case (II-4). This will be accomplished in part II of the paper.

## Added in proof:

The proofs of Theorem 6.14 and Lemmas 6.18, 6.22 and 6.23, also show:
Theorem 6.25. Suppose that Case(II-3) of Remark 3.11 occurs. Then, with $C$ replaced by a new minimal ( -1 )-curve $E$, one of the following cases occurs:
(1) Cases in $\S 3.1$ and §5. (2) The case in Lemma 6.3, or the case in Lemma 6.22, Claim(2), (3) Case(II-4) of Remark 3.11.
