# A Brooks Type Integral with Respect to a Set-Valued Measure

By Anca-Maria Precupanu

**Abstract.** A generalization of the set–valued Brooks integral [3] with respect to a set–valued measure whose values are subsets of a Hausdorff locally convex topological vector space is presented.

The construction of this new kind of integral is based on Weber's result [19] concerning the existence of a family of semi-invariant pseudometrics which generates the uniformity of a uniform semigroup (in our case, the semigroup of convex, bounded, closed subsets of a Hausdorff locally convex topological vector space).

Several properties of the new integral are given and also a theorem of Vitali type is established.

# 1. Introduction

In recent years, the study of set-valued measures has been developed extensively because of their applications in the mathematical economics, optimization and optimal control [11],[16],[17].

Significant contributions in this area were made by Artstein [2], Castaing–Valadier [4], Costé [5], Alò, de Korvin and Roberts [1], Brooks [3], Drewnowski [7], Godet–Thobie [9], Papageorgiou [13],[14], Hiai [10].

We recall that, recently, Papageorgiou [14] introduced a set-valued integral with respect to a h-set-valued measure in the sense of Alò, de Korvin and Roberts [1], of bounded variation using the set of Bochner integrals of a Banach valued function with respect to measure selectors of the given multimeasure.

Our purpose is to define a new kind of integral using Brooks' procedure [3] adapted in the setting of a set-valued measure whose values are subsets of a Hausdorff locally convex topological vector space X and with respect to the  $\Gamma_{\mu}$ -convergence in submeasure defined with the aid of a family of

<sup>1991</sup> Mathematics Subject Classification. Primary 28B20; Secondary 28A25, 28B10.

pseudometrics which generates the uniformity of the semigroup  $\mathcal{K}(X)$  of the convex, closed, bounded subsets of X.

Very briefly the organization of the paper is as follows. In section 2 we precise the terminology and notations, recall some properties of multimeasures and some basic results concerning the  $\Gamma_{\mu}$ -convergence in submeasure. In section 3 we define and study some basic properties of the integral of simple functions and in section 4 we present our set-valued integral with some natural properties and we prove a theorem of Vitaly-type for this kind of integral.

# 2. Terminology and notations

Let X be a Hausdorff locally convex topological vector space (briefly H.l.c.t.v.s.),  $\tau$  its topology and  $\mathcal{V}$  a base of absolutely convex closed neighborhoods of the origin 0 in X.  $\mathcal{A}(X)$  is the family of all nonvoid subsets of X,  $\mathcal{C}(X)$  is the subfamily of  $\mathcal{A}(X)$  of all closed subsets of X and  $\mathcal{K}(X)$  is the subfamily of  $\mathcal{A}(X)$  of convex, closed, bounded subsets of X.

On  $\mathcal{A}(X)$  we define the equivalence relation " $\rho$ " by  $A\rho B$  iff  $\overline{A} = \overline{B}$ , where  $\overline{A}$  denotes the closure of  $A \subset X$  with respect to  $\tau$ .

The quotient  $\mathcal{A}(X)/\rho$  may be identified with  $\mathcal{C}(X)$ . It is easy to see that the addition  $(A, B) \longrightarrow A + B$  in  $\mathcal{A}(X)$  is compatible with  $\rho$ . Hence  $(\mathcal{A}(X), +)$  admits a factorization by  $\rho$  and the resulting quotient semigroup may be identified with  $(\mathcal{C}(X), +)$ , where + is the Minkowski addition that is

 $A + B = \overline{A + B}$ , for every  $A, B \in \mathcal{A}(X)$ 

(see [7]).

Now let  $\mathcal{U}$  be the invariant uniformity on X compatible with  $\tau$  and  $\tilde{\mathcal{U}}$  the exponential extension of  $\mathcal{U}$  to  $\mathcal{A}(X)$ , that is the uniformity  $\tilde{\mathcal{U}}$  defined by the following base of vicinities:

$$\mathcal{W}(U) = \{ (A, B) \in \mathcal{A}(X) \times \mathcal{A}(X); \ A \subset B + U, \ B \subset A + U \}, \ (\forall) U \in \mathcal{U}.$$

The topology on  $\mathcal{A}(X)$  induced by  $\tilde{\mathcal{U}}$  will be denoted by  $\tilde{\tau}$ .

Using the equivalence relation  $\rho$  we may identify  $(\mathcal{A}(X), \tilde{\tau})/\rho$  with  $(\mathcal{C}(X), \tilde{\tau})$ and the separated uniform space associated with  $(\mathcal{A}(X), \tilde{\mathcal{U}})/\rho$  with  $(\mathcal{C}(X), \tilde{\mathcal{U}})$ .

534

In particular, if X is metrizable, then  $(\mathcal{A}(X), \tilde{\mathcal{U}})$  becomes a semimetrizable space for the Hausdorff semimetric between sets; if, besides, X is complete, then so is  $\mathcal{C}(X)$ .

When  $\tau$  is determined by a norm  $\|\cdot\|$ , the Hausdorff semimetric is given by

$$d(A,B) = \inf\{t > 0; \ A \subset B + tU_1, \ B \subset A + tU_1\},\$$

where  $U_1 = \{x \in X; \|x\| \le 1\}.$ 

If  $(X, \mathcal{U})$  is a complete uniform space, then so is  $(\mathcal{C}(X), \hat{\mathcal{U}})$ . It is easy to see that  $(\mathcal{C}(X), \dot{+}, \tilde{\mathcal{U}})$  is a Hausdorff uniform commutative semigroup with the unit  $\{0\}$  and  $\mathcal{K}(X)$  is a closed subsemigroup in which the cancellation law

$$A \dot{+} C = B \dot{+} C \implies A = B$$

holds in it.

Instead of  $\{0\}$  we will usually write simply 0. According to a result of Weber [19] there exists a family  $\mathcal{P} = \{p\}$  of semiinvariant pseudometrics on  $\mathcal{C}(X)$  taking values in [0,1], which generates the uniformity  $\tilde{\mathcal{U}}$ . (A pseudometric p is semiinvariant if  $p(A \dotplus C, B \dotplus C) \leq p(A, B)$  for every  $A, B, C \in \mathcal{C}(X)$ .)

If 
$$p \in \mathcal{P}$$
 we denote by

(2) 
$$|A|_p = p(A, 0),$$

where 0 represents the set  $\{0\}$ .

From the semiinvariance of  $p \in \mathcal{P}$  we easily obtain the following properties:

(3) 
$$|A + B|_p \le |A|_p + |B|_p, \quad (\forall) A, B \in \mathcal{C}(X),$$

(4) 
$$|A + B|_p \ge |A|_p - |B|_p, \quad (\forall) A, B \in \mathcal{C}(X).$$

Beside X we consider S a nonvoid set,  $\mathcal{P}(S)$  the family of all subsets of S and  $\mathcal{R}$  a ring of subsets of S.

In the following we shall consider set-valued maps  $\mu$  from S to X, that is set-valued functions  $\mu$  defined on  $\mathcal{R}$  taking values in the semigroup  $\mathcal{K}(X)$ with the supplementary property  $\mu(\emptyset) = 0$ .

DEFINITION 2.1. A set-valued map  $\mu$  from  $\mathcal{R}$  to X is said to be:

I. an additive set-valued measure (multimeasure) if

(5) 
$$\mu(A \cup B) = \mu(A) \dot{+} \mu(B), \quad (\forall)A, B \in \mathcal{R} \text{ with } A \cap B = \emptyset;$$

II. a  $\sigma$ -additive multimeasure if for every sequence  $(A_n)_{n\geq 1} \subset \mathcal{R}$  with  $A_i \cap A_j = \emptyset \ (i \neq j)$  and  $\bigcup_{n=1}^{\infty} A_n \in \mathcal{R}$  holds

(6) 
$$\mu\left(\bigcup_{n=1}^{\infty}A_n\right) = \sum_{n=1}^{\infty}\mu(A_n)$$

(the sum from the right side of the equality is considered with respect to the topology  $\tilde{\tau}$  and the Minkowski addition +).

In what follows by a set–valued measure or a multimeasure we shall mean an additive set–valued measure.

DEFINITION 2.2. Let  $\mu$  be a set-valued measure from  $\mathcal{R}$  to X and  $p \in \mathcal{P}$  an arbitrary pseudometric from the family  $\mathcal{P}$ .

The function  $\tilde{\mu}_p : \mathcal{R} \longrightarrow \overline{\mathbb{R}}_+$  defined by

(7) 
$$\tilde{\mu}_p(A) = \sup\left\{\sum_{i=1}^n |\mu(A_i)|_p\right\},$$

where the supremum is taken on all finite partitions  $(A_i)_{i=1}^n$  of  $A \in \mathcal{R}$  with  $A_i \in \mathcal{R}$  is said to be the *p*-variation of  $\mu$ .

It is easy to see that if  $\mu$  is additive (respectively  $\sigma$ -additive) so is  $\tilde{\mu}_p$ .  $\tilde{\mu}_p$  may be extended to  $\mathcal{P}(S)$  by

(8) 
$$\tilde{\mu}_p(E) = \inf\{\tilde{\mu}_p(A); E \subseteq A \in \mathcal{R}\}, \quad (\forall) E \in \mathcal{P}(S)$$

which is a submeasure in Drewnowski sense [6].

Now  $\mathcal{P}(S)$  may be organized as a ring with respect to symmetrical difference  $\Delta$  as addition and the intersection  $\cap$  as product.

Furthermore the family  $\Gamma_{\mu} = \{\tilde{\mu}_{p}^{*}; p \in \mathcal{P}\}\$  of submeasures on  $\mathcal{P}(S)$  generates a topology  $\tau_{\Gamma_{\mu}}$  on  $\mathcal{P}(S)$  such that  $(\mathcal{P}(S), \Delta, \cap; \tau_{\Gamma_{\mu}})$  becomes a topological ring for which the family  $\mathcal{B}_{\Gamma_{\mu}}$  of subsets  $V_{k,\varepsilon} = \{A \subset S; \tilde{\mu}_{p}^{*}(A) < \varepsilon, p \in K\}$ , where K is a finite subset in  $\mathcal{P}$  and  $\varepsilon > 0$ , is a base of neighborhoods of  $\emptyset$  for this topology [6].

In what follows we shall write  $\mathcal{P}(S)(\Gamma_{\mu})$  for  $(\mathcal{P}(S), \Delta, \cap; \tau_{\Gamma_{\mu}})$  and  $\mathcal{R}(\Gamma_{\mu})$  for a topological subring  $\mathcal{R}$  of  $\mathcal{P}(S)(\Gamma_{\mu})$ .

536

We shall also denote by  $\mathcal{R}_{\mu}$  the hereditary subring of  $\mathcal{R}$  of all  $\Gamma_{\mu}$ integrable members of  $\mathcal{R}$  that is the family of all sets  $A \in \mathcal{R}$  such that  $\tilde{\mu}_p(A) < \infty$  for every  $p \in \mathcal{P}$ .

If  $\mu$  is a set-valued measure from  $\mathcal{R}$  to X, then  $\mu$  satisfies the following property:

( $\alpha$ ) For every  $B \in \mathcal{R}_{\mu}$  and for every vicinity W from  $\tilde{\mathcal{U}}$  in  $\mathcal{K}(X)$  there exists  $\varepsilon > 0$  such that for every finite family  $\{(\alpha_i, \beta_i)\}_{i=1}^n$  of real numbers such that  $|\alpha_i - \beta_i| < \varepsilon$ ,  $(\forall)i = 1, 2, ..., n$  and for every finite disjoint sequence  $(A_i)_{i=1}^n$  of subsets of  $\mathcal{R}$ , the following relation holds

$$\left(\sum_{i=1}^n \alpha_i \mu(A_i \cap B), \sum_{i=1}^n \beta_i \mu(A_i \cap B)\right) \in W.$$

Next we denote by  $\mathbb{I}\!\!R^S$  the set of all functions f from S to  $\mathbb{I}\!\!R$ . For every finite  $K \subset \mathcal{P}$  and  $\varepsilon > 0$  we consider

$$W_K(\varepsilon) = \{ (f,g) \in \mathbb{R}^S \times \mathbb{R}^S; \ \tilde{\mu}_p^* (\{s \in S; |f(s) - g(s)| \ge \varepsilon\}) < \varepsilon, p \in K \}.$$

The family of all subsets  $W_k(\varepsilon)$  constitutes a base of vicinities for a uniformity  $\mathcal{U}_{\Gamma_{\mu}}$  on  $\mathbb{R}^S$ .

We shall also use the notation  $I\!\!R^S(\Gamma_\mu)$  for  $(I\!\!R^S, \mathcal{U}_{\Gamma_\mu})$ .

DEFINITION 2.3. A net  $(f_{\alpha})$  from  $\mathbb{R}^{S}$  is said to be *convergent in*  $\Gamma_{\mu}$ submeasure to  $f \in \mathbb{R}^{S}$ , denoted  $f_{\alpha} \xrightarrow{\Gamma_{\mu}} f$ , if  $f_{\alpha}$  converges to f in  $\mathbb{R}^{S}(\Gamma_{\mu})$ .

Remarking that the function  $\varphi$  which associates to every  $E \in \mathcal{P}(S)$  its indicatrice function is an isomorphism between the uniform space  $\mathcal{P}(S)(\Gamma_{\mu})$ and the uniform subspace Y of  $\mathbb{R}^{S}(\Gamma_{\mu})$  of all indicatrice functions of subsets of S, where  $\mathbb{R}$  is endowed with its natural uniform structure, it is legitimate to use the notation  $E_{\alpha} \xrightarrow{\Gamma_{\mu}} E$  for the convergence in  $\mathcal{P}(S)(\Gamma_{\mu})$ .

### 3. Integration of simple functions

DEFINITION 3.1. A function  $f \in \mathbb{R}^S$  is said to be a simple  $\Gamma_{\mu}$ -integrable function if: a) it assumes only a finite number of distinct values  $a_i \in \mathbb{R}$ ; b)  $f^{-1}(\{a_i\}) = A_i \in \mathbb{R}$ ; c) if  $a_i \neq 0$  then  $A_i \in \mathbb{R}_{\mu}$ .

In this case if  $T \in \mathcal{R}$  the integral of f over T is defined by

(9) 
$$\int_{T} f d\mu = \sum_{i=1}^{n} a_{i} \mu(T \cap A_{i}).$$

We remark that if  $\chi_T$  denotes the characteristic function of T, then  $f = \sum_{i=1}^n a_i \chi_{A_i}$ .

It is easy to see that the integral of f is independent of the representation of f as a finite combination of this type.

In what follows we shall denote by  $\mathcal{E}(\Gamma_{\mu}, X)$ , or briefly  $\mathcal{E}(\Gamma_{\mu})$ , the set of all  $\Gamma_{\mu}$ -integrable simple functions.

From the definition 3.1 we immediately obtain

THEOREM 3.2. If  $f, g \in \mathcal{E}(\Gamma_{\mu})$ , then:

I. 
$$f + g \in \mathcal{E}(\Gamma_{\mu})$$
 and  $\int_{T} (f + g) d\mu = \int_{T} f d\mu + \int_{T} g d\mu$ ,  $(\forall) T \in \mathcal{R}$ ;

- II. for every  $p \in \mathcal{P}$ ,  $p(\int_{\mathcal{T}} f d\mu, \int_{\mathcal{T}} g d\mu) \leq \int_{\mathcal{T}} |f g| d\mu_p$ ,  $(\forall) T \in \mathcal{R}$ .
- III. the set-valued map  $\nu(T) = \int_T f d\mu$ ,  $(\forall)T \in \mathcal{R}$ , is a multimeasure and if moreover  $\mu$  is  $\sigma$ -additive then so is  $\nu$ .

IV. 
$$\lim_{T \xrightarrow{\Gamma_{\mu}} \emptyset} \int_{T} f d\mu = 0.$$

PROOF. I), III) and IV) may be immediately obtained from the definition 3.1.

To prove II) let  $f = \sum_{i=1}^{n} a_i \chi_{A_i}$  and  $g = \sum_{j=1}^{m} b_j \chi_{B_j}$ . We observe that it is possible to find a finite family  $(E_k)_{k=1}^s \subset \mathcal{R}$  such that  $f = \sum_{k=1}^{s} a_k \chi_{E_k}$ and  $g = \sum_{k=1}^{s} b_k \chi_{E_k}$ . Next, for every  $p \in \mathcal{P}$  we have

$$p\left(\int_{T} f d\mu, \int_{T} g d\mu\right) = p\left(\sum_{k=1}^{s} a_{k}\mu(T \cap E_{k}), \sum_{k=1}^{s} b_{k}\mu(T \cap E_{k})\right) \leq \\ \leq \sum_{k=1}^{s} p(a_{k}\mu(T \cap E_{k}), b_{k}\mu(T \cap E_{k})) \leq \\ \leq \sum_{k=1}^{s} |a_{k} - b_{k}| \mu(T \cap E_{k})|_{p} \leq$$

$$\leq \sum_{k=1}^{s} |a_k - b_k| \tilde{\mu}_p(T \cap E_k). \square$$

THEOREM 3.3. Let  $(f_{\alpha})_{\alpha \in I}$  be a Cauchy net in  $\mathbb{R}^{S}(\Gamma_{\mu})$  of simple  $\Gamma_{\mu}$ integrable functions.

The net  $(\int_T f_\alpha d\mu)_{\alpha \in I}$  is uniformly Cauchy with respect to  $T \in \mathcal{R}$  if and only if the following two conditions hold:

- I. for every neighborhood V of the origin in  $\mathcal{K}(X)$  there exists  $\alpha_0 \in I$ and a neighborhood  $\mathcal{V}_{\mu}$  of  $\emptyset$  in  $\mathcal{R}(\Gamma_{\mu})$  such that  $\int_T f_{\alpha} d\mu \in V$  for every  $\alpha \geq \alpha_0$  and every  $T \in \mathcal{V}_{\mu}$ ;
- II. for every neighborhood V of the origin in  $\mathcal{K}(X)$  there exist  $\alpha_0 \in I$  and  $M \in \mathcal{R}_{\mu}$  such that  $\int_T f_{\alpha} d\mu \in V$  for every  $\alpha \geq \alpha_0$  and every  $T \in \mathcal{R}$  with  $T \subset S \setminus M$ .

PROOF. First let us assume that the net  $(\int_T f_\alpha d\mu)_{\alpha \in I}$  is uniform Cauchy with respect to  $T \in \mathcal{R}$  and let V be an arbitrary neighborhood of the origin in  $\mathcal{K}(X)$ . Then there exists a symmetrical vicinity W from  $\tilde{\mathcal{U}}$  such that  $W^2(0) \subset V$ . By virtue of hypothesis there exists  $\alpha_0 \in I$  such that  $(\int_T f_\alpha d\mu, \int_T f_{\alpha_0} d\mu) \in W$  for every  $T \in \mathcal{R}$  and  $\alpha \geq \alpha_0$ . Now, from the theorem 3.2, IV), there exists a neighborhood  $\mathcal{V}_\mu$  of  $\emptyset$  in  $\mathcal{R}(\Gamma_\mu)$  such that  $\int_T f_{\alpha_0} d\mu \in W(0)$  for  $T \in \mathcal{V}_\mu$ . Hence  $\int_T f_\alpha d\mu \in V$  for  $\alpha \geq \alpha_0$  and  $T \in \mathcal{V}_\mu$  that is I) is satisfied. To obtain II) it is sufficient to take  $M = \{s \in S; f_{\alpha_0} \neq 0\}$ . We see that  $M \in \mathcal{R}_\mu$  and  $\int_T f_{\alpha_0} d\mu = 0$  for every  $T \in \mathcal{R}$  with  $T \subset S \setminus M$ , that is II) is proved.

Conversely, let  $W_1$  be a vicinity of  $\tilde{\mathcal{U}}$  and W a symmetrical vicinity of  $\tilde{\mathcal{U}}$  such that that  $W^2 + W^2 + W^2 \subset W_1$  (W exists because of the uniform continuity of the addition in  $\mathcal{K}(X)$ .)

Let  $j_0 \in J$ ,  $\mathcal{V}_{\mu}$  and  $M \in \mathcal{R}_{\mu}$  corresponding to W(0) by virtue of hypotheses I) and II). ( $\alpha_0$  can be chosen to satisfy simultaneously I) and II).

According to  $(\alpha)$  from section 1, to M and W it corresponds  $\delta > 0$ such that for every  $n \in N$ , every  $\{(\alpha_i, \beta_i)\}_{i=0}^n$  with  $\alpha_i, \beta_i \in \mathbb{R}$  such that  $|\alpha_i - \beta_i| < \delta, i = 0, 1, 2, ..., n$  and  $(E_i)_{i=0}^n$ , a finite disjoint sequence of members of  $\mathcal{R}$ , the following relation holds

$$\left(\sum_{i=0}^{n} \alpha_{i} \mu(E_{i} \cap M), \sum_{i=0}^{n} \beta_{i} \mu(E_{i} \cap M)\right) \in W.$$

Let  $M_{\alpha,\alpha'} = \{s \in S; |f_\alpha(s) - f_{\alpha'}(s)| \ge \delta\}.$ 

We see that  $M_{\alpha,\alpha'} \in \mathcal{R}$  for every  $\alpha, \alpha' \in J$  and since  $(f_{\alpha})$  is a Cauchy net in  $\mathbb{R}^{S}(\Gamma_{\mu})$  there exists  $\alpha_{1} \geq \alpha_{0}$  such that  $M_{\alpha,\alpha'} \in \mathcal{V}_{\mu}$  for  $\alpha \geq \alpha_{1}$  and  $\alpha' \geq \alpha_{1}$ .

Now, taking into account that  $W^2 + W^2 + W^2 \subset W_1$  we obtain for every  $T \in \mathcal{R}$ ,

$$\begin{split} \left( \int_{T} f_{\alpha} d\mu, \int_{T} f_{\alpha'} d\mu \right) &= \left( \int_{T \cap M_{\alpha,\alpha'}} f_{\alpha} d\mu, \int_{T \cap M_{\alpha,\alpha'}} f_{\alpha'} d\mu \right) + \\ &+ \left( \int_{T \setminus (M_{\alpha,\alpha'} \cup M)} f_{\alpha} d\mu, \int_{T \setminus (M_{\alpha,\alpha'} \cup M)} f_{\alpha'} d\mu \right) + \\ &+ \left( \int_{(T \setminus M_{\alpha,\alpha'}) \cap M} f_{\alpha} d\mu, \int_{(T \setminus M_{\alpha,\alpha'}) \cap M} f_{\alpha'} d\mu \right) \in \\ &\in W(0) \times W(0) + W(0) \times W(0) + W^{2} \subseteq \\ &\subseteq W^{2} + W^{2} + W^{2} \subset W_{1} \end{split}$$

for every  $\alpha \geq \alpha_1, \alpha' \geq \alpha_1$ ; hence the net  $\{\int_T f_\alpha d\mu\}$  is uniform Cauchy with respect to  $T \in \mathcal{R}$ .  $\Box$ 

### 4. Integration with respect to a multimeasure

LEMMA 4.1. Let  $\{f_{\alpha}\}_{\alpha \in I}$  and  $\{g_{\beta}\}_{\beta \in J}$  be two nets in  $\mathcal{E}(\Gamma_{\mu}, X)$  both convergent in  $\mathbb{R}^{S}(\Gamma_{\mu})$  to the same function. If  $(\int_{T} f_{\alpha} d\mu)$  and  $(\int_{T} g_{\beta} d\mu)$ are Cauchy nets uniformly with respect to  $T \in \mathcal{R}$ , then for every vicinity W from  $\tilde{\mathcal{U}}$ , there are  $\alpha_{0}$  and  $\beta_{0}$  such that for every  $\alpha \geq \alpha_{0}$  and  $\beta \geq \beta_{0}$ ,  $(\int_{T} f_{\alpha} d\mu, \int_{T} g_{\beta} d\mu) \in W$  uniformly in  $T \in \mathcal{R}$ .

PROOF. Let W be a vicinity from  $\tilde{\mathcal{U}}$  and let  $W_1$  be a symmetrical vicinity of  $\tilde{\mathcal{U}}$  such that  $W^2 + W^2 + W^2 \subset W_1$ .

Let  $\delta > 0$  corresponding to  $W_1$  by virtue of the condition ( $\alpha$ ).

We denote by  $M_{\alpha,\beta} = \{s \in S; |f_{\alpha}(s) - g_{\beta}(s)| > \delta\}.$ 

Using the theorem 3.3 we obtain  $\alpha_0, \beta_0$ , a  $\Gamma_{\mu}$ -integrable set M in S and a neighborhood  $\mathcal{V}_{\mu}$  of  $\emptyset$  in  $\mathcal{R}(\Gamma_{\mu})$  such that  $\int_T f_{\alpha} d\mu \in W_1(0)$  and  $\int_T g_{\beta} d\mu \in$  $W_1(0)$  for  $\alpha \geq \alpha_0, \beta \geq \beta_0, T \in \mathcal{V}_{\mu}$  with  $T \subset S \setminus M, T \in \mathcal{R}$ .

540

By virtue of hypotheses there exist  $\alpha_1 \geq \alpha_0$  and  $\beta_1 \geq \beta_0$  such that  $M_{\alpha,\beta} \in \mathcal{V}_{\mu}$  for  $\alpha \geq \alpha_1$  and  $\beta \geq \beta_1$  and every  $T \in \mathcal{R}$ .

In the same way as in theorem 3.3 we find that  $(\int_T f_\alpha d\mu, \int_T g_\beta d\mu) \in W$ for  $\alpha \ge \alpha_1, \beta \ge \beta_1$  and every  $T \in \mathcal{R}$ .  $\Box$ 

DEFINITION 4.2. A function  $f \in \mathbb{R}^S$  is said to be  $\Gamma_{\mu}$ -integrable if there exists a net  $\{f_{\alpha}\}$  in  $\mathcal{E}(\Gamma_{\mu})$  such that  $f_{\alpha} \xrightarrow{\Gamma_{\mu}} f$  and  $\{\int_T f_{\alpha} d\mu\}$  is a Cauchy net in  $\mathcal{K}(X)$  uniform with respect to  $T \in \mathcal{R}$ .

In this case the element of the completion  $\mathcal{K}(X)$  of  $\mathcal{K}(X)$  defined by  $\int_T f d\mu = \lim_{\alpha} \int_T f_{\alpha} d\mu$  is said to be the  $\Gamma_{\mu}$ -integral of f on  $T \in \mathcal{R}$ .

By virtue of Lemma 4.1 the notion of  $\Gamma_{\mu}$ -integral is well-defined.

REMARK. If X is a Banach space and  $\mathcal{C}(X)$  is endowed with Hausdorff distance, then  $\mathcal{C}(X)$  becomes a complete metric space in which  $\mathcal{K}(X)$  is a closed subspace, that is also complete.

Now, let  $\mu$  be a multimeasure from S to X,  $\nu$  its variation and  $\nu^*$  the corresponding submeasure defined as in (8). Then the  $\Gamma_{\mu}$ -integral of a function  $f \in \mathbb{R}^S$ , defined as in definition 4.2 is just the integral studied by Brooks in [3].

In what follows we shall denote by  $\mathcal{L}(\Gamma_{\mu}, X)$  the set of all  $\Gamma_{\mu}$ -integrable functions.

Evidently  $\mathcal{E}(\Gamma_{\mu}, X) \subset \mathcal{L}(\Gamma_{\mu}, X)$ .

Now we can obtain some remarkable properties of  $\Gamma_{\mu}$ -integrable functions.

THEOREM 4.3. If  $f, g \in \mathcal{L}(\Gamma_{\mu}, X)$  we have:

- I.  $f + g \in \mathcal{L}(\Gamma_{\mu}, X)$  and  $\int_{T} (f + g) d\mu = \int_{T} f d\mu + \int_{T} g d\mu$ ,  $(\forall) T \in \mathcal{R}$ ;
- II. the set-valued map defined by  $\nu(T) = \int_T f d\mu$ ,  $(\forall)T \in \mathcal{R}$ , is a multimeasure and if moreover  $\mu$  is  $\sigma$ -additive then so is  $\nu$ ;
- III.  $\lim_{\substack{E \xrightarrow{\Gamma_{\mu}}\\ E \in \mathcal{R}}} \nu(E) = 0;$

Anca-Maria Precupanu

IV. if 
$$S \notin \mathcal{R}_{\mu}$$
, then the family  $\{B_M\}_{M \in \mathcal{R}_{\mu}}$ , where the nonvoid set  $B_M$  is  
associated to  $M \in \mathcal{R}_{\mu}$  by  $B_M = \{T \in \mathcal{R}; T \cap M = \emptyset\}$  constitutes a  
filterbase  $\mathcal{F}$  on  $\mathcal{R}$  and for every  $f \in \mathcal{L}(\Gamma_{\mu}, X)$ ,  $\lim_{\mathcal{F}} \int_T f d\mu = 0$ .

PROOF. We immediately obtain I) and II) from the definition 4.2 and the analogous properties for simple integrable functions (see theorem 3.2).

To prove III) let W be a symmetrical vicinity of  $\mathcal{K}(X)$ , the completion of  $\mathcal{K}(X)$ , and let  $g \in \mathcal{E}(\Gamma_{\mu}, X)$  such that  $(\int_{T} f d\mu, \int_{T} g d\mu) \in W$  for every  $T \in \mathcal{R}$ .

Let  $\mathcal{V}_{\mu}$  be a neighborhood of  $\emptyset$  in  $\mathcal{R}(\Gamma_{\mu})$  such that  $\int_{T} g d\mu \in W(0)$  for  $T \in \mathcal{V}_{\mu}$ . But  $\int_{T} f d\mu \in W^{2}(0)$  for  $T \in \mathcal{V}_{\mu}$  that is III) is satisfied.

To prove IV) it is sufficient to remark that  $M = \{s \in S; g(s) \neq 0\}$  is  $\Gamma_{\mu}$ -integrable and then for  $T \in B_M$  we have  $\int_T f d\mu \in W(0)$  that is IV).  $\Box$ 

THEOREM 4.4. Let  $\{f_{\alpha}\}_{\alpha\in D}$  be a net of  $\Gamma_{\mu}$ -integrable functions, Cauchy in  $\mathbb{R}^{S}(\Gamma_{\mu})$ . The net  $\{\int_{T} f_{\alpha}d\mu\}_{\alpha\in D}$  is uniform Cauchy with respect to  $T \in \mathcal{R}$  if and only if the following two conditions are satisfied:

- I. for every neighborhood V of the origin in  $\tilde{K}(X)$  there exist an index  $\alpha_0$  and a neighborhood  $\mathcal{V}_{\mu}$  of  $\emptyset$  in  $\mathcal{R}(\Gamma_{\mu})$  such that  $\int_T f_{\alpha} d\mu \in V$  for  $\alpha \geq \alpha_0$  and  $T \in \mathcal{V}_{\mu}$ ;
- II. for every neighborhood V of the origin in  $\tilde{K}(X)$  there exist an index  $\alpha_0 \in D$  and a  $\Gamma_{\mu}$ -integrable set M such that  $\int_T f_{\alpha} d\mu \in V$  for  $\alpha \geq \alpha_0$ , and  $T \in \mathcal{R}, T \subset S \setminus M$ .

PROOF. The necessity can be obtained in the same way as in the theorem 3.3 using the theorem 4.3, III) and IV).

Conversely, let  $\{f_{\alpha}\}_{\alpha \in D}$  be a Cauchy net in  $\mathbb{R}^{S}(\Gamma_{\mu})$  of  $\Gamma_{\mu}$ -integrable functions which satisfies the conditions I) and II) from theorem.

By virtue of the  $\Gamma_{\mu}$ -integrability of  $f_{\alpha}$ , for every  $\alpha \in D$ , there exists a net  $\{f_{\alpha,\beta}\}_{\beta\in D_{\alpha}}$  in  $\mathcal{E}(\Gamma_{\mu}, X)$  such that  $f_{\alpha,\beta} \xrightarrow{\Gamma_{\mu}} f_{\alpha}$  and  $\lim_{\beta} \int_{T} f_{\alpha,\beta} d\mu = \int_{T} f_{\alpha} d\mu$  uniformly in  $T \in \mathcal{R}$ .

Now let us consider  $\{f_{\alpha,\varphi(\alpha)}; (\alpha,\varphi) \in D \times \prod_{\alpha} D_{\alpha}\}$  the diagonal approximation associated to  $\{f_{\alpha,\beta}; \alpha \in D, \beta \in D_{\alpha}\}$  (see Kelley [12], Chap.II). If U is a symmetrical vicinity in  $\mathbb{R}^{S}(\Gamma_{\mu})$  there exists  $\varphi_{U} \in \prod_{\alpha} D_{\alpha}$  such that for every  $\varphi \in \prod_{\alpha} D_{\alpha}$  with  $\varphi \geq \varphi_{U}$  we obtain  $(f_{\alpha}, f_{\alpha,\varphi(\alpha)}) \in U$  for every  $\alpha \in D$ . But  $\{f_{\alpha}\}_{\alpha \in D}$  is a Cauchy net in  $\mathbb{R}^{S}(\Gamma_{\mu})$  and then for U there exists  $\alpha_{1} \in D$  such that  $(f_{\alpha}, f_{\alpha'}) \in U$  for  $\alpha \geq \alpha_{1}$  and  $\alpha' \geq \alpha_{1}$ . From here we obtain  $(f_{\alpha,\varphi(\alpha)}, f_{\alpha',\varphi(\alpha')}) \in U^{3}$  for  $(\alpha,\varphi) \geq (\alpha_{1},\varphi_{U})$  and  $(\alpha',\varphi') \geq (\alpha_{1},\varphi_{U})$ , that is  $\{f_{\alpha,\varphi(\alpha)}\}_{\alpha \in D}$  is a net in  $\mathcal{E}(\Gamma_{\mu}, X)$  which is Cauchy in  $\mathbb{R}^{S}(\Gamma_{\mu})$ .

Now let  $V_0$  be a neighborhood of the origin in  $\tilde{\mathcal{K}}(X)$  and let W be a symmetrical vicinity of  $\tilde{\mathcal{K}}(X)$  such that  $W^2(0) \in V_0$ .

For this W(0) there exist  $\alpha_0, \mathcal{V}_{\mu}$  and M such that the conditions I) and II) of theorem are simultaneously satisfied.

Then there exists  $\varphi_1 \in \prod_{\alpha \in D} D_\alpha$  such that for every  $\varphi \in \prod_{\alpha} D_\alpha$  with  $\varphi \geq \varphi_1$  we have  $(\int_T f_{\alpha,\varphi(\alpha)} d\mu, \int_T f_\alpha d\mu) \in W$  for every  $\alpha \in D$  and every  $T \in \mathcal{R}$ .

Now if  $(\alpha, \varphi) \geq (\alpha_0, \varphi_1)$  we obtain  $\int_T f_{\alpha,\varphi(\alpha)} d\mu \in V_0$  for  $T \in \mathcal{V}_{\mu}$  or  $T \in \mathcal{R}$  with  $T \subset S \setminus M$ , that is the net  $\{\int_T f_{\alpha,\varphi(\alpha)} d\mu\}$  is a Cauchy net uniform with respect to  $T \in \mathcal{R}$ . Consequently, there exists  $\alpha_1$  such that for  $\alpha \geq \alpha_1$  and  $\alpha' \geq \alpha_1$  we have  $(\int_T f_{\alpha} d\mu, \int_T f_{\alpha'} d\mu) \in W^2$  uniformly in  $T \in \mathcal{R}$  whence the theorem follows.  $\Box$ 

REMARK. On  $\mathcal{L}(\Gamma_{\mu}, X)$  we can introduce a uniform structure which we shall call the uniform structure of the  $\Gamma_{\mu}$ -mean.

To see this let  $\mathcal{W}$  be the uniform structure on  $\mathcal{K}(X)$ . For every  $W \in \mathcal{W}$  we consider

$$E_W = \{ (f,g) \in \mathcal{L}(\Gamma_\mu, X) \times \mathcal{L}(\Gamma_\mu, X); (\int_T f d\mu, \int_T g d\mu) \in W, \ (\forall) T \in \mathcal{R} \}.$$

It is easy to see that the family  $\{E_W\}_{W \in \mathcal{W}}$  is a base of vicinities for a uniform structure  $\mathcal{T}_W$  on  $\mathcal{L}(\Gamma_{\mu}, X)$ .

Let  $\mathcal{M}(\mathcal{L}(\Gamma_{\mu}, X))$  be the uniform structure induced on  $\mathcal{L}(\Gamma_{\mu}, X)$  by  $\mathbb{R}^{S}(\Gamma_{\mu})$ .

The uniform structure on  $\mathcal{L}(\Gamma_{\mu}, X)$  defined by  $\sup\{\mathcal{M}(\mathcal{L}(\Gamma_{\mu}, X)), \mathcal{T}_W\}$  is said to be the uniform structure of the  $\Gamma_{\mu}$ -mean convergence.

The convergence of a net  $\{f_{\alpha}\}_{\alpha \in D}$  to f with respect to this uniformity considered on  $\mathcal{L}(\Gamma_{\mu}, X)$  is called then *convergence in*  $\Gamma_{\mu}$ -mean and we denote it by  $f_{\alpha} \longrightarrow f$  ( $\Gamma_{\mu}$ -mean). DEFINITION 4.5. A net  $\{f_{\alpha}\}_{\alpha \in D}$  of  $\Gamma_{\mu}$ -integrable functions is said to be  $\Gamma_{\mu}$ -equiintegrable if  $\{f_{\alpha}\}$  satisfies the conditions I) and II) of theorem 4.4.

Now, we can prove a Vitali type theorem.

THEOREM 4.6. Let  $\{f_{\alpha}\}_{\alpha \in D}$  be a net of  $\mathcal{L}(\Gamma_{\mu}, X)$ . Then a function  $f \in \mathbb{R}^{S}$  is  $\Gamma_{\mu}$ -integrable and  $f_{\alpha} \longrightarrow f$  ( $\Gamma_{\mu}$ -mean) if and only if the following two conditions hold:

- I.  $f_{\alpha} \xrightarrow{\Gamma_{\mu}} f;$
- II.  $\{f_{\alpha}\}_{\alpha \in D}$  is a  $\Gamma_{\mu}$ -equiintegrable net.

PROOF. The necessity may be easily obtained from the theorem 4.4.

Conversely, let  $\{f_{\alpha}\}_{\alpha \in D}$  be a net of  $\mathcal{L}(\Gamma_{\mu}, X)$  which satisfies the conditions I) and II) of the theorem. For every  $\alpha \in D$  there exists a net  $\{f_{\alpha,\beta}\}_{\beta \in D_{\alpha}}$  of  $\mathcal{E}(\Gamma_{\mu}, X)$  such that  $f_{\alpha,\beta} \longrightarrow f(\Gamma_{\mu}\text{-mean})$ .

Let  $\{f_{\alpha,\varphi(\alpha)}; \alpha \in D, \varphi \in \prod_{\alpha} D_{\alpha}\}$  be the corresponding diagonale approximation. As in the proof of the theorem 4.4 we obtain that  $f_{\alpha,\varphi(\alpha)} \longrightarrow f(\Gamma_{\mu}$ -mean) and then  $f \in \mathcal{L}(\Gamma_{\mu}, X)$ .

Moreover  $\lim_{\alpha,\varphi} \int_T f_{\alpha,\varphi(\alpha)} d\mu = \int_T f d\mu$  uniformly with respect to  $T \in \mathcal{R}$ . Now let W be a summatrical visibility of  $\tilde{\mathcal{K}}(X)$ 

Now let W be a symmetrical vicinity of  $\mathcal{K}(X)$ .

There exists  $(\alpha_1, \varphi_1) \in D \times \prod_{\alpha} D_{\alpha}$  such that for every  $(\alpha, \varphi) \ge (\alpha_1, \varphi_1)$ ,  $(\int_T f d\mu, \int_T f_{\alpha,\varphi(\alpha)} d\mu) \in W$  and  $\int_T f_{\alpha,\varphi(\alpha)} d\mu, \int_T f_{\alpha} d\mu) \in W$ , uniformly in  $T \in \mathcal{R}$ .

If  $\alpha \geq \alpha_1$ , then  $(\int_T f_\alpha d\mu, \int_T f d_\mu) \in W^3$  uniformly in T whence the theorem follows.  $\Box$
