Trivializable subriemannian structures and
spectral analysis of associated operators

Abstract. In this talk we first recall the notion of a subriemannian manifold $M$ and we provide various examples. Under some additional assumptions it is known that a subriemannian structure induces a hypo-elliptic non-negative operator $\Delta^{\text{sub}}$ which is called sub-Laplacian. In the cases where $M$ is a sphere (of a certain dimension) or a general compact two step nilmanifold we study the heat kernel and the spectrum of $\Delta^{\text{sub}}$. The results are compared with the heat kernel and the spectrum of the Laplacian on $M$. Similar to the case of Riemannian manifolds to which the Beltrami-Laplace operator is assigned to, one can study the relation between the subriemannian geometry of $M$ and spectral invariants with respect to $\Delta^{\text{sub}}$. This presentation is based on a joint work with K. Furutani (Tokyo University of Science, Japan) and C. Iwasaki (University of Hyogo, Japan).
